# **About the Center for Health Policy**

The Center for Health Policy (CHP) is the research hub of the Department of Health Policy and Management. Our mission is to generate evidence that informs decision-making in Indiana and beyond. CHP Fellows and staff conduct rigorous research and evaluation on health system performance and health policy issues, with a specific focus on: population health and analytics; substance misuse and mental health services; and public health systems and services research.

The CHP has a vibrant research portfolio including funding from the National Institutes of Health (NIH), the Agency for Healthcare Research and Quality (AHRQ), the Robert Wood Johnson Foundation, various state agencies in Indiana, and numerous other government agencies nationwide.

The Center is directed by Dr. Joshua Vest.

# INTRODUCTION

In July 2005, Indiana's Office of the Governor received a grant from the U.S. Department of Health and Human Services' Center for Substance Abuse Prevention (CSAP) as part of CSAP's Strategic Prevention Framework State Incentive Grant (SPF SIG) program. The SPF SIG program represented a continuation of ongoing CSAP initiatives encouraging states to engage in data-based decision-making in the area of substance use prevention planning and grant-making.

This grant was made on the heels of an earlier CSAP State Incentive Grant (SIG), which laid much of the groundwork for this new initiative. A great deal of work was completed under the first SIG to assess substance abuse prevention services and develop a strategic framework to guide policymaking in this area for the 21st century. The final report summarizing the outcomes of this work, entitled *Imagine Indiana Together: The Framework to Advance the Indiana Substance Abuse Prevention System*, was prepared by the Governor's Advisory Panel within the Division of Mental Health and Addiction (DMHA), Indiana Family and Social Services Administration. This report is available from DMHA and the Indiana Prevention Resource Center at Indiana University Bloomington.

As a requirement of the SPF SIG initiative, the State established a State Epidemiological Outcomes Workgroup (SEOW) to facilitate data-based decisionmaking regarding substance use prevention programming through the collection, analysis, and reporting of available epidemiological data. After the end of the Indiana SPF SIG in 2010, the State decided to continue supporting the work of the SEOW as part of its long-term efforts to improve substance abuse prevention policy.

This report represents the 13th official *State Epidemiological Profile* completed by the SEOW. As in past years, we have updated the core set of analyses to reflect the most recent data available. In order to make the report most useful for state and local policymakers and service providers, we present detailed information and descriptive analyses regarding the patterns and consequences of substance use both for the state and, whenever possible, each of Indiana's 92 counties.

This report summarizes findings on alcohol, tobacco, marijuana, opioid (prescription-type and illegal), and stimulant use/misuse. In addition, we included data on mental health and suicide, since both substance use and mental distress are highly correlated and frequently co-occur. These data come from a variety of sources, including national and Indiana-based surveys as well as de-identified administrative records.

As with our prior reports, our primary aim in preparing this annual document is to provide a useful reference tool for policymakers, communities, and professionals involved in substance use prevention and mental health promotion. We realize not everyone has the time or energy to review the contents in detail. For this reason, we again are offering drug fact sheets with summaries on each of the major substances. The full report, as well as earlier versions and supplemental resources, are available on the Center for Health Policy website (https://fsph.iupui.edu/research-centers/centers/ health-policy). The website also has links to a series of issue briefs related to drug misuse and other behavioral health topics; these briefs are developed each year as part of the SEOW's work. Furthermore, in 2018 we added a Data Portal; i.e., an online tool that allows users to review and interact with data tables, graphs, and maps.

We appreciate your interest and leadership in addressing the problem of substance misuse in Indiana, and, as always, we welcome your feedback on this report and our work.

#### Center for Health Policy

# **EXECUTIVE SUMMARY**

Substance use continues to be a major public health concern, negatively impacting a variety of health, legal, and social outcomes. Nearly one-fourth of Hoosiers ages 12 and older engaged in binge drinking in the past month and one-tenth used an illicit substance. Furthermore, 7% of Indiana residents met criteria for substance use disorder (SUD) in the past year and 6.5% needed but did not receive treatment for their SUD (Substance Abuse and Mental Health Services Administration [SAMHSA], 2017).

Of particular concern is polysubstance use, i.e., the use of two or more substances over a defined period, simultaneously or at differing times, for recreational purposes. In over 70% of admissions to substance use treatment in Indiana, the use of multiple substances was indicated, with 30% reporting the use of two drugs and nearly 41% reporting the use of three drugs (Indiana Family and Social Services Administration [FSSA], 2018).

During state fiscal year 2018, a total of 10,483 children were removed from their parents by the Department of Child Services in Indiana; almost twothirds (64%) of these removals were due to parental alcohol and/or drug use (Indiana Department of Child Services, 2018).

#### Alcohol

Alcohol is the most frequently used substance in Indiana and the United States. Just under half of the population ages 12 and older consumed alcohol within the past month (SAMHSA, 2017). Indiana and U.S. rates of underage drinking among 12- to 17-year-olds were similar (IN: 9.2%; U.S.: 9.6%).

Excessive alcohol consumption contributes to a number of health and economic consequences. Prolonged and compulsive use of alcohol can lead to alcohol use disorder. In 2017, almost one-fourth of Indiana residents ages 12 or older reported binge drinking, which was similar to the national rate (IN: 23.1%; U.S.: 24.4%). About 5% of Hoosiers suffered from alcohol use disorder (AUD) within the past year (U.S.: 5.5%). The highest rate of AUD was found among 18- to 25-year-olds (IN: 10.7%; U.S.: 10.4%) (SAMHSA, 2017).

Alcohol-related collisions decreased from 13,911 in 2003 to 7,733 in 2017. The number of fatal crashes also decreased from 242 to 158 (Indiana State Police, 2017). However, age-adjusted mortality rates for alcoholattributable deaths have climbed gradually from 2000 through 2017 in both Indiana and the United States. Indiana's age-adjusted rate was 9.6 per 100,000 in 2017, which is the same as the national rate (Centers for Disease Control and Prevention [CDC], 1999-2017).

In addition to health consequences and mortality, alcohol misuse has disproportionately contributed to the United States' economic burden. In 2010, excessive alcohol consumption cost the United States \$249 billion, with Indiana attributing \$4.5 billion (CDC, 2017).

#### **Tobacco / Nicotine**

Even though cigarette smoking has declined in recent years, tobacco use is still a public health issue. Cigarette smoking and tobacco-related diseases cost the United States more than \$300 billion per year (CDC, 2018b). In 2017, nearly 22% of Indiana adults reported smoking cigarettes (down from almost 26% in 2011). Indiana's smoking rates have been consistently higher than the national rates (CDC, 2018a).

The decline of cigarette smoking has given rise to other tobacco products. E-cigarettes, hookahs, and other tobacco products gained more popularity and market themselves as safer than cigarettes (Indiana State Department of Health, Tobacco Prevention and Cessation Commission [ISDH/TPCC], 2015). Approximately 23.7% of adults in Indiana reported trying an e-cigarette in 2017 (ISDH/TPCC, 2018). E-cigarettes appeal particularly to younger people and are currently the most commonly used tobacco product among youth. About 24% of Indiana high school students and 22% of Indiana college students reported current use of e-cigarettes (CDC, 1991-2015; King & Jun, 2018).

Tobacco is the leading cause of preventable disease and death in the United States. Tobacco causes 6 million deaths worldwide, about 600,000 of which are from secondhand smoke exposure (World Health Organization, 2015). The U.S. experiences more than 480,000 deaths from tobacco use, about 41,000 of which are from secondhand smoke exposure (CDC, 2018b). In Indiana, more than 11,100 adults die every year from smoking, and 333,000 live with a tobacco-related disease (U.S. Department of Health and Human Services [USDHHS], 2014).

#### **Opioids**

Opioid misuse and addiction have created a national crisis in the United States. According to 2017 data from the National Survey on Drug Use and Health (NSDUH), almost 5% of Indiana residents ages 12 or older misused prescription pain relievers (U.S.: 4.2%) and 0.6% reported using heroin in the past year (U.S.: 0.3%) (SAMHSA, 2017). Rates were generally higher among young adults ages 18 to 25 for both pain relievers (IN: 8.8%; U.S.: 7.1%) and heroin (IN: 1.3%; U.S.: 0.6%) (SAMHSA, 2017).

Opioid treatment programs (OTPs) provide medication-assisted treatment to individuals with opioid use disorder. In Indiana, a total of 13,697 unique patients were treated in OTPs in 2017 (FSSA, 2018). According to the Treatment Episode Data Set (TEDS), in nearly 21% of Indiana treatment admissions, misuse of prescription opioids was reported, and in over 22% of treatment admissions, heroin use was reported (SAMHSA, 2016).

Morbidity and mortality related to opioids increased significantly over the past seven years. Non-fatal emergency department visits due to an opioid overdose rose from 1,856 in 2011 to 8,169 in 2017 (from 45 to 123 visits per 100,000 population) (ISDH, 2018). Overdose deaths involving opioids rose from 347 in 2011 to 1,138 in 2017 (from 5 to 17 deaths per 100,000 population) (ISDH, 2018).

#### **Other Illicit Drugs**

Marijuana is the most commonly used illicit drug in the United States (Azofeifa et al., 2016). In 2017, past-month use of marijuana was reported by over 9% of Indiana residents ages 12 and older and past-year use by more than 14%. Prevalence was highest among individuals ages 18 to 25, with nearly 21% of Hoosiers in this age group reporting current marijuana use and 34% reporting past-year use. Indiana and U.S. rates were comparable (SAMHSA, 2017). In nearly half of Indiana treatment admissions, marijuana use was reported (U.S.: 33%) (SAMHSA, 2016).

Stimulants encompass both legal (prescription stimulants such as Ritalin and Adderall) and illicit drugs (such as cocaine and methamphetamine). Almost 2% of Indiana residents ages 12 and older used cocaine in the past year, which was similar to the U.S. rate. Cocaine use was highest among young adults ages 18 to 25, with 6% reporting past year use (SAMHSA, 2017).

Admissions data indicate that methamphetamine was the most widely used stimulant among Hoosiers receiving substance use treatment in 2016. In almost 24% of admissions, methamphetamine use was reported; a percentage significantly higher than the nation's 17%. Cocaine was the second most frequently used stimulant in Indiana's treatment population and was reported in 12% of admissions; a percentage significantly lower than that noted for the rest of the nation (18%). Less than 2% of the treatment population in Indiana and the U.S. reported the use of other stimulants at the time of admission.

#### Center for Health Policy

## ALCOHOL USE IN INDIANA: CONSUMPTION PATTERNS AND CONSEQUENCES

#### INTRODUCTION

Alcohol is the most frequently used substance in both Indiana and the United States. In 2016, the National Institute on Alcohol Abuse and Alcoholism (NIAAA) estimated that Hoosiers 14 years and older consumed 11,756 gallons of ethanol (the intoxicating agent in alcoholic beverages). By volume, this equates to 118,132 gallons of beer, 12,321 gallons of wine, or 11,802 gallons of spirits. This level of use represents an annual per capita consumption rate of 2.2 gallons of ethanol for Hoosiers age 14 and older (NIAAA, 2018). In 2017, there were 12,999 alcohol beverage permits on file in Indiana, representing a rate of 1.8 licenses per 1,000 Hoosiers; thus, Indiana residents have many points of access to alcohol (Alcohol and Tobacco Commission, 2017).

Alcohol's legal status, its wide availability, and its social acceptability are all contributors to patterns of excessive or risky use, such as heavy drinking or binge drinking. Excessive consumption of alcohol is responsible for significant morbidity and mortality due to alcohol-related health problems (e.g., cirrhosis and other serious liver diseases), alcohol use disorders, homicides, suicides, violent crimes, and vehicle crashes. Additionally, other health-compromising behaviors such as cigarette smoking, illicit drug use, and risky sexual behaviors have also been linked to drinking (CDC, 2016).

Alcohol use can also contribute to adverse social outcomes such as job loss and involvement with the criminal justice and social service system. In 2010, the most recent year for which estimates are available, Indiana spent \$4.5 billion to deal with the negative consequences of excessive alcohol use, with much of these expenses tied to outcomes associated with binge drinking (Sacks, Gonzales, Bouchery, Tomedi, & Brewer, 2015).

#### PREVALENCE OF ALCOHOL CONSUMPTION IN THE GENERAL POPULATION

#### National Survey on Drug Use and Health

Based on 2016–2017 averages from the Substance Abuse and Mental Health Services Administration (SAMHSA)'s National Survey on Drug Use and Health (NSDUH), an estimated 49.9% (95% Confidence Interval [CI]: 47.1-52.7) of Indiana residents 12 years of age or older had used alcohol in the past month; Indiana's prevalence rate for current alcohol use<sup>1</sup> was similar to the U.S. rate of 51.2% (95% CI: 50.8-51.7) (see Figure 2.1). Young adults between the ages of 18 and 25 reported the highest level of use. Rates were similar between Indiana residents in that age group (59.8%; 95% CI: 55.8-63.7) and their national counterparts (56.7%, 95% CI: 55.9–57.6). Furthermore, 9.2% (95% CI: 7.6–11.2) of young people ages 12 to 17 consumed alcohol in the past 30 days in Indiana (see Figure 2.2); the rate was similar on the national level (9.6%; 95% CI: 9.1-10.0).

NSDUH also provides underage drinking estimates for 12- to 20-year-olds. In 2017, Indiana's rate for current alcohol use in underage Hoosiers (20.2%; 95% CI: 17.8–22.7) was similar to that of the U.S. (19.5%; 95% CI: 18.8–20.2) (SAMHSA, 2017).

<sup>1</sup>Current alcohol use is defined as having used alcohol in the past 30 days or past month.

**Figure 2.1** Percentage of Indiana and U.S. Population (12 Years and Older) Reporting Current Alcohol Use (National Survey on Drug Use and Health, 2008–2017)

Source: SAMHSA, 2017

**Figure 2.2** Percentage of Indiana Population Reporting Current Alcohol Use by Age Group (National Survey on Drug Use and Health, 2008–2017)

Source: SAMHSA, 2017

In 2015, SAMHSA redesigned the questions on the NSDUH pertaining to binge drinking. The definition of binge drinking for women was lowered from five or more drinks on one occasion to four or more drinks (for men, it remained at five or more drinks). 2016 is the first year for which both national- and state-level estimates are

available. These new estimates of binge drinking cannot be compared with estimates from previous years (Center for Behavioral Health Statistics and Quality, 2016). Based on the new definition for binge drinking, the NSDUH estimated that in 2017, 23.1% of Indiana's population 12 years of age or older reported binge drinking (95%)

**Figure 2.3** Current Binge Drinking in Indiana and the U.S. by Age Group (National Survey on Drug Use and Health, 2017)

Source: SAMHSA, 2017

Table 2.1Percentage of Indiana Adults Having UsedAlcohol in the Past 30 Days, by Gender, Race/Ethnicity,and Age Group (Behavioral Risk Factor SurveillanceSystem, 2017)

		Indiana % (95% CI)
Gender	Male	58.7% (57.0–60.4)
	Female	45.0% (43.4–46.6)
Race/Ethnicity	White	51.9% (50.7-53.2)
	Black	50.3% (45.7–54.8)
	Hispanic	50.4% (45.2–55.7)
Age Group	18-24	52.9% (48.4–57.3)
	25-34	63.8% (60.5–67.0)
	35-44	58.4% (55.3–61.5)
	45-54	53.8% (51.2–56.4)
	55-64	48.9% (46.7–51.1)
	65+	36.5% (34.9–38.1)
Total		51.6% (50.5–52.8)

Source: CDC, 2018

CI: 20.8–25.5); this represents a rate similar to the national average of 24.4% (95% CI: 24.0–24.8). Binge drinking was more prevalent among 18- to 25-year-olds than among any other age group (U.S.: 37.6%; 95% CI: 36.9–38.4; IN: 38.2%; 95% CI: 34.3–42.4). Binge drinking rates in 2017 in underaged individuals were similar in Indiana (12.5%; 95% CI: 10.7–14.5) and the U.S. (12.0%; 95% CI: 11.5–12.5) (SAMHSA, 2017) (see Figure 2.3).

# Behavioral Risk Factor Surveillance System

Based on findings from the Centers for Disease Control and Prevention (CDC)'s Behavioral Risk Factor Surveillance System (BRFSS), adult prevalence rates for current alcohol use in 2017 were 51.6% (95% CI: 50.5– 52.8) for Indiana and 54.7% for the nation. In Indiana, rates tended to be higher among males and among younger age groups (see Table 2.1) (CDC, 2018).

**Figure 2.4** Percentage of Indiana and U.S. Adults Reporting Binge Drinking in the Past 30 Days (Behavioral Risk Factor Surveillance System, 2011–2017)

Source: CDC, 2018

Table 2.2Percentage of Indiana Residents WhoEngaged in Binge Drinking in the Past 30 Days, byGender, Race/Ethnicity, and Age Group (Behavioral RiskFactor Surveillance System, 2017)

		1
		Indiana % (95% Cl)
Gender	Male	22.3% (20.8–23.8)
	Female	11.2% (10.1–12.3)
Race/Ethnicity	White	16.4% (15.4–17.4)
	Black	14.9% (11.7–18.2)
	Hispanic	21.6% (16.9–26.2)
Age Group	18-24	24.4% (20.8–28.1)
	25-34	27.1% (24.1–30.1)
	35-44	19.7% (17.2–22.2)
	45-54	17.6% (15.6–19.6)
	55-64	10.5% (9.1–11.8)
	65+	5.0% (4.3–5.8)
Total		16.6% (15.7–17.5)

Source: CDC, 2017

The BRFSS defines binge drinking as "males having five or more drinks on one occasion and females having four or more drinks on one occasion." The overall prevalence rate for adult binge drinking in Indiana (16.6%, 95% CI: 15.7–17.5) was similar to the U.S. median rate (17.4%) in 2017.

Statewide, binge alcohol use was significantly higher in males and more prevalent in younger individuals (see Table 2.2). Trends in binge drinking are shown in Figure 2.4 (CDC, 2018).

#### Youth Risk Behavior Surveillance System

According to the CDC's Youth Risk Behavior Surveillance System (YRBSS), in 2015, 30.5% (95% CI: 26.3–35.2) of Indiana high school students had consumed at least one alcoholic drink in the past 30 days. No significant differences in alcohol consumption were observed by gender or race/ethnicity; however, rates varied by grade level, with 9th grade students reporting the lowest rate. Indiana's past-month alcohol prevalence among high school students was similar to the nation's rate (32.8%: 95% CI: 30.4–35.2). Furthermore, 17.4% (95% CI: 14.0– 21.5) of Indiana high school students reported having had five or more alcoholic drinks within a couple of hours at least once in the past month; the U.S. rate was similar at 17.7% (95% CI: 15.8–19.8). Indiana's binge alcohol consumption among high school students decreased significantly from 28.9% in 2003 to 17.4% in 2015 (CDC, 1991–2015).

#### **Indiana Youth Survey**

The Indiana Youth Survey (INYS) indicates that in 2018, 29.5% of Indiana 12th grade students reported using

alcohol at least once during the past 30 days (Gassman et al., 2018). Overall, alcohol consumption patterns seemed to progress with age; i.e., 8th grade students showed lower prevalence rates than 10th and 12th grade students. For more detailed data on monthly alcohol use among Indiana and U.S. 8th, 10th, and 12th grade students, see Figure 2.5; for trend information (from 2009 through 2018) on monthly alcohol use among high school seniors, see Figure 2.6. For monthly and binge use by Indiana region and grade for 2018, see Appendix 2A.

#### Indiana College Substance Use Survey

The Indiana Prevention Resource Center (IPRC) developed the Indiana College Substance Use Survey (ICSUS) to measure alcohol and other drug usage, attitudes, and perceptions among college students at two- and four-year institutions. According to 2018 results, 63.3% of respondents reported past-month alcohol use; past-month consumption rates were significantly lower for underage students (53.1%) than for those ages 21 and older (80.0%). Similarly, past-month binge drinking prevalence (overall 36.7%) was significantly lower for underage students (31.0%) than for those ages 21 and older (46.2%) (King & Jun, 2018).<sup>2</sup>

#### USE OF ALCOHOL IN THE TREATMENT POPULATION National Survey on Drug Use and Health

Based on 2016–2017 NSDUH averages, the estimated prevalence for alcohol use disorder<sup>3</sup> in the past year among those ages 12 and older was 5.2% (95% CI: 4.3–6.3) in Indiana, which was similar to the national estimate (5.5%; 95% CI: 5.3–5.6) (see Figure 2.7). Of all age groups, adults ages 18 to 25 reported the highest prevalence rates both in Indiana and nationally across all years reviewed. Additionally, an estimated 4.9% (95% CI: 4.1–5.9) of those ages 12 and older were in need of but did not receive treatment for alcohol use in Indiana (U.S.: 5.2%; 95% CI: 5.1–5.4) (SAMHSA, 2017).

<sup>2</sup>Twenty-four (24) Indiana colleges participated in the 2018 survey; results are based on nonrandom sampling and are not representative of all college students in Indiana.

<sup>3</sup>The NSDUH defines alcohol use disorder as meeting the criteria for "dependence" or "abuse" based on definitions found in the 4th edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)*.

#### **Treatment Episode Data Set**

According to the Treatment Episode Data Set (TEDS), alcohol plays a major role in admissions to substance abuse treatment. In nearly half (47.8%) of Indiana treatment episodes in 2016, alcohol use was reported (U.S.: 46.9%), and in 29.6%, alcohol dependence<sup>4</sup> was indicated (U.S.: 32.6%) (see Figure 2.8) (SAMHSA, 2015).

Source: SAMHSA, 2017

**Figure 2.8** Percentage of Treatment Episodes in Indiana and the United States with Alcohol Use and Alcohol Dependence Reported at Treatment Admission (Treatment Episode Data Set, 2007–2016)

Source: SAMHSA, 2016

<sup>4</sup>We defined alcohol dependence as "individuals in substance abuse treatment listing alcohol as their primary substance at admission."

#### Center for Health Policy

Factors significantly associated with alcohol use in Indiana's treatment population included gender, race/ ethnicity, and age:

**Gender**—A higher percentage of males (53.8%) in substance abuse treatment reported alcohol use, compared to 41.4% of females.

**Race/ethnicity**—Nearly half (45.5%) of whites in treatment reported using alcohol at the time of admission; this percentage was higher for blacks (59.5%) and other races (52.5%). With regard to ethnicity, a significantly higher percentage of Hispanics (61.6%) reported alcohol use than non-Hispanics (47.2%).

**Age**—The percentage of Hoosiers reporting alcohol use at treatment admission increased with age and was highest among those ages 55 and older (74.5%).

Table 2.3 depicts the percentage of Indiana residents, categorized by gender, race, ethnicity, and age group, reporting alcohol use at treatment admission. See Appendix 2B, for county-level treatment data.

# CONSEQUENCES OF ALCOHOL USE Hospitalizations

Hospital discharge records show that in 2017, a total of 7,116 hospitalized patients were treated in Indiana for an alcohol-attributable primary diagnosis, representing one percent (0.9%) of all hospital discharges in the state (Indiana State Department of Health [ISDH], 2017).<sup>5</sup>

#### **Fetal Alcohol Spectrum Disorders**

Alcohol consumption during pregnancy is another major health concern since fetal alcohol spectrum disorders (FASD) are a direct result of prenatal exposure to alcohol. FASD is not a clinical diagnosis, but an umbrella term used to describe a range of disorders such as fetal alcohol syndrome, alcohol-related neurodevelopmental disorder, and alcohol-related birth defects. Possible Table 2.3Percentage of Treatment Episodes inIndiana Reporting Alcohol Use at Treatment Admission,by Gender, Race, Ethnicity, and Age Group (TreatmentEpisode Data Set, 2016)

		Alcohol Dependence
Gender	Male	53.8%
	Female	38.9%
Race	White	45.5%
	Black	59.5%
	Other	52.5%
Ethnicity	Hispanic	61.6%
	Non-Hispanic	47.2%
Age Group	Under 18	42.1%
	18-24	39.9%
	25-34	39.3%
	35-44	51.0%
	45-54	68.2%
	55+	74.5%
Total		47.8%

Source: SAMHSA, 2016

physical effects include brain damage; facial anomalies; growth deficiencies; defects of heart, kidney, and liver; vision and hearing problems; skeletal defects; and dental abnormalities. In the United States, the prevalence of fetal alcohol spectrum disorders is 10.0 per 1,000 live births (SAMHSA, Fetal Alcohol Spectrum Disorders Center for Excellence, 2007).

The Indiana Birth Defects and Problems Registry collects information on birth defects and birth problems for all children in Indiana from birth to 3 years old (5 years old for autism and fetal alcohol syndrome). State law requires doctors, hospitals, and other healthcare providers to submit a report to the registry at ISDH when a child is born with a birth defect. From 2015 through 2017, 61 children were born with fetal alcohol syndrome,<sup>6</sup> the most severe form of FASD, in Indiana (ISDH, 2015–2017).

<sup>6</sup>The ICD-9 code for fetal alcohol syndrome is 760.71.

<sup>&</sup>lt;sup>5</sup>For our analysis, we only included primary diagnoses that were 100% attributable to alcohol, as listed in CDC's Alcohol-Related Disease Impact (ARDI) database. These included ICD-10 codes E24.4 (Alcohol-induced pseudo-Cushing's syndrome), F10 (Mental and behavioral disorders due to use of alcohol), G31.2 (Degeneration of nervous system due to alcohol), G62.1 (Alcoholic polyneuropathy), G72.1 (Alcoholic myopathy), I42.6 (Alcoholic cardiomyopathy), K29.2 (Alcoholic gastritis), K70 (Alcoholic liver disease), K86.0 (Alcohol-induced chronic pancreatitis), R78.0 (Finding of alcohol in blood), X45 (Accidental poisoning by and exposure to alcohol), Y15 (Poisoning by and exposure to alcohol, undetermined cause) (CDC, 2006-2010).

#### **Alcohol-Related Mortality**

From 2000 through 2016, a total of 8,034 Hoosiers died from alcohol-induced causes, and mortality rates attributable to alcohol have climbed gradually in both Indiana and the United States (CDC, 1999–2017).<sup>7</sup> In

2017, Indiana's age-adjusted alcohol-attributable death rate was 9.6 per 100,000 (95% CI: 8.9–10.3); the same as the U.S. rate (95% CI: 9.5–9.7) (see Figure 2.9) (CDC, 1999–2017).

Source: CDC, 1999-2017

<sup>7</sup>Alcohol-induced causes of death include the following ICD-10 codes: E24.4, F10, G31.2, G62.1, G72.1, I42.6, K29.2, K70, K86.0, R78.0, X45, X65, Y15.

Appendix 2C, lists conditions that can be attributed to alcohol, along with their alcohol-attributable percentages. The list was developed through CDC's Alcohol-Related Disease Impact (ARDI) database (CDC, 2006–2010).

#### **Alcohol-Related Motor Vehicle Accidents**

Data from the Automated Reporting Information Exchange System (ARIES), part of the Indiana State Police's Vehicle Crash Records System, showed a decrease in alcoholrelated collisions from 13,911 in 2003 to 7,733 in 2017. This represents a 44% drop. The number of fatal crashes with alcohol involvement also decreased, from 242 to 158, representing a 35% drop. (For a detailed listing of alcohol-related collisions and fatalities in Indiana by county for 2017, see Appendix 2D). The overall rate for alcoholrelated collisions in Indiana in 2017 was 1.2 per 1,000 population (Indiana State Police, 2017).

# Child Removals due to Parental Substance Abuse

During SFY 2018, a total of 10,483 children were removed from their homes. In 847 cases (8.1%), parental alcohol abuse was indicated as the reason for removal (Indiana Department of Child Services, 2019).<sup>8</sup> [See Appendix 2E for county-level information.]

# Alcohol, Tobacco, and/or Drug-Related School Suspensions or Expulsions

In Indiana, students can be suspended or expelled from school for using alcohol, tobacco, and/or drugs on school property. Data from the Indiana Department of Education (IDOE) indicate that during the academic year 2018, a total of 1,006 suspensions/expulsions were recorded in Indiana schools related to alcohol (IDOE, 2019). [See Appendix 2F for county-level information.]

<sup>8</sup>Counts and percentages may underrepresent removals that involve parental alcohol and/or drug abuse as data relies on parent alcohol and/or drug abuse being selected as a removal reason. There may be instances where alcohol and/or drug abuse is present but not selected as the removal reason.

#### **APPENDIX 2A**

Percentage of Indiana Students Reporting Monthly and Binge Alcohol Use, by Region and Grade (Indiana Youth Survey, 2018)

		Indiana	Northwest	North Central	Northeast	West	Central	East	Southwest	Southeast

Notes: We defined alcohol dependence as "individuals in substance abuse treatment listing alcohol as their primary substance at admission."

We calculated the percentages by dividing the number of reported alcohol use/dependence by the number of treatment episodes.

Information on treatment episodes <5 was suppressed due to confidentiality constraints.

#### **APPENDIX 2C**

Conditions that are Directly Attributable to Alcohol in Indiana (Alcohol-Related Disease Impact, Based on Averages from 2006–2010)

	Percentage		Percentage
	Directly Attributable		Directly Attributable
Condition	to Alcohol	Condition	to Alcohol
Alcohol abuse/dependence	100%	Chronic pancreatitis	84%
Alcohol cardiomyopathy	100%	Gastroesophageal hemorrhage	47%
Alcohol polyneuropathy	100%	Homicide	47%
Alcohol-induced chronic pancreatitis	100%	Fire Injuries	42%
Alcoholic gastritis	100%	Hypothermia	42%
Alcoholic liver disease	100%	Esophageal varices	40%
Alcoholic myopathy	100%	Liver cirrhosis, unspecified	40%
Alcoholic psychosis	100%	Portal hypertension	40%
Degeneration of nervous system due to alcohol	100%	Drowning	34%
Fetal alcohol syndrome/Fetus and newborn		Fall injuries	32%
affected by maternal alcohol use	100%	Poisoning (not alcohol)	29%
Alcohol poisoning	100%	Acute pancreatitis	24%
Excessive blood alcohol level	100%	Suicide	23%
Suicide by and exposure to alcohol	100%

# **TOBACCO USE IN INDIANA: CONSUMPTION PATTERNS AND CONSEQUENCES**

#### INTRODUCTION

In the United States, one of every five deaths is related to cigarette smoking, making it the leading cause of preventable disease and death (U.S. Department of Health and Human Services [USDHHS], 2014). The adverse effects of tobacco on population health have been well-researched. In Indiana, more than 11,100 adults die every year from their own smoking, and 333,000 live with a tobacco-related disease (USDHHS, 2014). Furthermore, 151,000 (approximately 1 in 10) Indiana youth now under the age of 18 will die prematurely from a smoking-related illness (USDHHS, 2014). Additionally, over 1,300 adults, children, and infants died in 2014 as a result of exposure to secondhand smoke (Lewis & Zollinger, 2014). Indiana incurs close to \$3 billion annually in healthcare costs directly caused by smoking, including nearly \$590 million that is absorbed by Medicaid (Campaign for Tobacco-Free Kids, 2018b).

Though self-reported cigarette smoking has been on the decline, electronic nicotine delivery systems, including e-cigarettes, have surged in popularity in recent years (Marynak et al., 2017). While e-cigarettes have been promoted as less dangerous than cigarettes, they have not been approved as safe by the U.S. Food and Drug Administration (FDA) and long-term health effects of exposure to aerosol from e-cigarettes are currently unknown (Indiana State Department of Health, Tobacco Prevention and Cessation Commission [ISDH/TPCC], 2018a).

#### PREVALENCE OF TOBACCO CONSUMPTION IN THE GENERAL POPULATION National Survey on Drug Use and Health

Estimates from the 2017 National Survey on Drug Use and Health (NSDUH) showed that 26.8% (95% Confidence Interval [CI]: 24.6 - 29.1) of Indiana residents 12 years and older used a tobacco product in the past month, a rate significantly higher than the U.S. rate (23.0%; 95% CI: 22.6–23.4). Tobacco products include cigarettes, smokeless tobacco, cigars, and pipe tobacco. Indiana's rate has gradually decreased over the past decade (see Figure 3.1) (Substance Abuse and Mental Health Services Administration [SAMHSA], 2017).

**Figure 3.1** Percentage of Indiana and U.S. Population (12 Years and Older) Reporting Any Tobacco Use in the Past Month (National Survey on Drug Use and Health, 2007–2017)

Source: SAMHSA, 2017
Among tobacco users, the most commonly used type of tobacco was cigarettes. In 2017, 21.4% (95% CI: 19.3-23.6) of Hoosiers ages 12 years and older reported past-month use of cigarettes, a rate significantly higher than the U.S. rate (18.5%; 95% CI: 18.1–18.8). Indiana's smoking prevalence declined from 28.0% in 2007 (95% CI: 25.6–30.4) to 21.4% in 2017 (95% CI: 19.3-23.6) (see Figure 3.2).

Source: SAMHSA, 2017

**Figure 3.3** Percentage of Indiana and U.S. Population (12 Years and Older) Reporting Cigarette Use in the Past Month (National Survey on Drug Use and Health, 2017)

Source: SAMHSA, 2017

Tobacco use differed by age group and was most prevalent among young adults. Over 28 percent of 18- to 25-year-olds in Indiana reported smoking cigarettes in the past month (95% CI: 20.9-27.9) compared to 24.3% of their national same-age counterparts (95% CI: 22.3-23.6) (see Figure 3.3) (SAMHSA, 2017).

#### **Behavior Risk Factor Surveillance System**

The Behavioral Risk Factor Surveillance System (BRFSS) focuses on behaviors and conditions that are linked to the leading causes of death. According to 2017 findings, the prevalence rate for adult smoking in Indiana was 21.8% (95% CI: 20.8–22.8). Moreover, 15.8% (95% CI: 14.9–16.7) of Hoosiers reported using cigarettes every day. Indiana's smoking rates were higher than the national median rates; i.e., 17.0% of U.S. adults smoked in the past month and 11.7% reported smoking every day (Centers for Disease Control and Prevention [CDC], 2018a). Statistically significant differences in smoking prevalence were observed for the following groups in Indiana (see Table 3.1):

- Smoking rates were higher among men than women.
- Smoking was less prevalent in Hispanic Hoosiers compared to those who identified as white or black.
- Smoking prevalence was lowest among older adults ages 65 and above.
- Educational attainment was inversely associated with prevalence rate, i.e., individuals who achieved higher levels of education had lower smoking rates.
- Income level was inversely associated with prevalence rate, i.e., individuals with higher income levels had lower smoking rates.

Adult smoking prevalence in Indiana continues to be above the U.S. level (see Figure 3.4).

**Table 3.1**Adult Smoking Prevalence in Indiana,by Gender, Race/Ethnicity, Age Group, EducationalAttainment, and Income Level (Behavioral Risk FactorSurveillance System, 2017)

		Indiana (95% Cl)
Gender	Male	23.5% (22.0 - 25.0)
	Female	20.2% (18.8 - 21.5)
Race / Ethnicity	White	22.3% (21.2 - 23.5)
	Black	21.3% (17.7 - 25.0)
	Hispanic	14.0% (10.3 - 17.6)
Age Group	18-24	18.7% (15.1 - 22.3)
	25-34	28.4% (25.3 - 31.5)
	35-44	26.1% (23.4 - 28.9)
	45-54	26.0% (23.7 - 28.4)
	55-64	23.3% (21.4 - 25.2)
	65+	10.4% (9.3 - 11.5)
Education	Less than High School	36.8% (32.8 - 40.9)
	High School or GED	26.5% (24.7 - 28.3)
	Some post-High School	21.1% (19.3 - 22.8)
	College Graduate	7.5% (6.5 - 8.5)
Income	Less than \$15,000	35.7% (31.9 - 39.4)
	\$15,000-\$24,999	32.5% (29.7 - 35.4)
	\$25,000-\$34,999	25.6% (22.3 - 28.9)
	\$35,000-\$49,999	22.7% (19.8 - 25.6)
	\$50,000 and above	14.2% (12.9 - 15.5)
Total		21.8% (20.8 - 22.8)

Source: CDC, 2017a

#### Indiana Adult Tobacco Survey

The 2017 Indiana Adult Tobacco Survey (IATS) estimated the overall smoking prevalence among Indiana adults at 23.6% (95% CI: 21.1–26.2). Smoking was most prevalent among persons:

- Without a high school degree (49.0%; 95% CI: 39.6– 58.5)
- With annual household incomes less than \$20,000 (42.4%; 95% CI: 32.7–52.7)
- Ages 25 to 39 years (32.9%; 95% CI: 27.0-39.4)

 Who are non-Hispanic black (30.9%; 95% CI: 22.5-40.8)

Approximately 23.7% (95% CI: 21.2-26.3) of adults in Indiana reported ever trying an e-cigarette.

Among current smokers, nearly one-third (31.5%; 95% CI: 25.7–38.0) reported intentions to quit within the next 30 days (Indiana State Department of Health [ISDH], Tobacco Prevention & Cessation Commission [TPCC], 2019). For details on smokers' intentions to quit, see Table 3.2.

**Figure 3.4** Percentage of Indiana and U.S. Population (18 Years and Older) Reporting Current Cigarette Use (Behavioral Risk Factor Surveillance System, 2011–2017)

Source: CDC, 2017a

	Within next 30 days	Within 30 days to 6 months	Sometime after 6 months	No intention to quit
Gender				
Male	28.2% (20.4–37.6)	15.3% (9.7–23.4)	14.6% (9.1–22.7)	41.9% (32.9–51.4)
Female	35.7% (27.3–45.0)	16.4% (10.8–24.0)	20.3% (14.0–28.5)	27.7% (20.3–36.4)
Race/Ethnicity				
White	28.4% (22.1–35.7)	15.3% (10.7–21.5)	17.7% (12.7–24.1)	38.6% (31.6–46.1)
Black	48.8% (31.8–66.1)	19.3% (8.9–36.8)	22.2% (10.7–40.4)	9.8% (4.0–21.8)
Hispanic	28.5% (7.2–67.2)	12.1% (1.6–53.3)	10.6% (1.4–49.6)	48.7% (17.9–80.6)
Other	43.0% (17.7–72.5)	10.8% (2.4–37.1)	20.6% (5.4–54.2)	25.7% (8.2–57.1)
Age Group				
18-24	23.0% (12.5–38.4)	14.3% (6.4–28.8)	17.7% (8.1–34.4)	45.0% (30.0–61.0)
25-39	34.2% (23.5–46.8)	17.8% (10.3–29.1)	18.4% (10.8–29.4)	29.6% (19.9–41.5)
40-64	33.6% (24.9–43.5)	14.4% (9.1–22.1)	18.8% (12.4–27.4)	33.2% (24.6–43.2)
65+	29.7% (15.8–48.7)	17.8% (7.1–37.9)	12.7% (3.7–35.3)	39.9% (23.2–59.4)
Education				
Less than High School	35.9% (22.3–52.1)	18.7% (9.2–34.5)	11.2% (5.0–23.3)	34.2% (21.2–50.1)
High School Grad	26.1% (18.3–35.8)	14.9% (9.1–23.4)	23.9% (15.9–34.4)	35.0% (25.8–45.5)
Some College	34.8% (24.6–46.6)	12.7% (7.2–21.3)	18.4% (11.1–28.9)	34.1% (24.5–45.3)
College	32.4% (16.6–53.5)	25.2% (12.0–45.4)	10.5% (2.6–33.6)	31.9% (15.9–53.7)
Post-Graduate	27.7% (8.3–61.9)	10.0% (1.9–39.0)	2.5% (0.5–10.7)	59.8% (28.8-84.6)
Income				
Less than \$20,000	39.0% (23.6–57.0)	13.3% (5.6–28.1)	18.6% (8.0–37.4)	29.2% (16.9–45.6)
\$20,000 - \$39,999	33.0% (22.1–46.0)	17.4% (9.4–30.0)	25.8% (16.6–37.8)	23.8% (15.3–35.1)
\$40,000 - \$69,999	32.5% (22.0–45.0)	18.8% (11.2–29.9)	14.6% (7.8–25.7)	34.2% (23.3–46.9)
\$70,000 or more	26.1% (17.1–37.8)	12.5% (6.9–21.5)	13.1% (6.9–23.4)	48.3% (36.6–60.2)
Total	31.5% (25.7–38.0)	15.7% (11.5–21.0)	17.9% (13.4–23.5)	34.9% (28.9–41.4)

Table 3.2	Intentions to Quit Smoking Among Current Smokers (Indiana Adult Tobacco Survey, 2017)	
-----------	---	--

Source: ISDH/TPCC, 2019

#### Indiana Youth Tobacco Survey

The Indiana Youth Tobacco Survey (IYTS) is a statewide school-based survey of middle school (grades 6 through 8) and high school (grades 9 through 12) students that captures information on various tobacco-related issues, such as tobacco use, smoking cessation, tobacco-related attitudes and beliefs, social influences on tobacco use, and secondhand smoke exposure. According to IYTS results, cigarette, smokeless tobacco products, and overall tobacco use declined significantly in Indiana from 2004 to 2016 (see Figures 3.5 and 3.6) (ISDH/TPCC, 2019).

Based on 2016 IYTS results, a total of 4.9% of middle school students (95% CI: 3.5–6.0) and 20.3% of high school students (95% CI: 15.4–25.6) used any tobacco product in the past month. Among middle school students, 1.8% (95% CI: 1.9–3.8) and among high school students, 8.7% (95% CI: 8.6–15.4) reported smoking cigarettes in

**Figure 3.5** Tobacco Use among Indiana High School Students (9th–12th Grade) (Indiana Youth Tobacco Survey, 2004–2016

Note: Due to the emergence of new tobacco products in recent years and corresponding changes to the survey instrument, the definition of "any tobacco use" has changed over time. Between 2004 and 2010, "any tobacco use" included cigarettes, cigars, smokeless tobacco, pipe, or bidis. In 2012, 2014, and 2016 "any tobacco use" included cigarettes, cigars, smokeless tobacco, bidis, pipe, hookah, snus, dissolvable tobacco, and e-cigarettes. Source: ISDH/TPCC, 2019

**Figure 3.6** Percentage of Indiana Middle School and High School Students Reporting Current Tobacco and Cigarette Use (Indiana Youth Tobacco Survey, 2004–2016)

Source: ISDH/TPCC, 2018

the past month. In 2016, 2.8% of middle school students and 10.5% of high school students in Indiana reported current use of e-cigarettes. Among Indiana youth who currently smoke cigarettes, 33.6% of middle school students and 45.8% of high school students also reported currently using e-cigarettes (ISDH/TPCC, 2019).

Appendix 3A shows the percentages, including 95% confidence intervals, of Indiana middle and high school students who reported current use of various tobacco products, grouped by gender, race/ethnicity, and grade, in 2016.

#### Youth Risk Behavior Surveillance System

The use of tobacco products has wide-ranging consequences for adolescents and young adults. Factors associated with youth tobacco use include low socioeconomic status; use and approval of tobacco use by peers or siblings; smoking by parents or guardians; accessibility, availability and price of tobacco products; a perception that tobacco use is normative; lack of parental support or involvement; low levels of academic achievement; lack of skills to resist influences to tobacco use; lower self-image or self-esteem; belief in functional benefits of tobacco use; and lack of self-efficacy to refuse offers of tobacco (CDC, 2016b).

The Youth Risk Behavior Surveillance System (YRBSS) monitors health-risk behaviors such as

tobacco, alcohol, and other drug use, which contribute to death and disability among youths in schools nationwide. According to 2015 YRBSS findings, almost one-third of high school students currently use a tobacco product, primarily electronic vapor products (vapor products) (see Table 3.3). In Indiana, rates of current cigarette use decreased significantly from 25.6% (95% CI: 23.2–28.2) in 2003 to 11.2% (95% CI: 8.3–14.8) in 2015; however, vapor products have gained popularity with nearly onefourth of high school students (23.9%; 95% CI: 20.6– 27.7) reporting current use (CDC, 1991-2015). For more information, see Figures 3.7 through 3.9.

Table 3.3	Current Use of Tobacco Products in Indiana
and U.S. Hi	gh School Students (Youth Risk Behavior
Surveillance	e System, 2015)

	Indiana (95% CI)	U.S.(95% CI)
Any Tobacco Use	32.4% (27.3–38.0)	31.4% (29.1–33.8)
Electronic Vapor Products	23.9% (20.6–27.7)	24.1% (22.1–26.2)
Cigarettes	11.2% (8.3–14.8)	10.8% (9.4–12.4)
Cigars	11.4% (9.1–14.3)	10.3% (9.0–11.8)
Smokeless Tobacco	9.4% (5.9–14.7)	7.3% (6.1–8.6)

Source: CDC, 1991-2015

**Figure 3.7** Rates of Current Use of Cigarettes and Electronic Vapor Products in Indiana High School Students (9th–12th Grade), by Gender (Youth Risk Behavior Surveillance System, 2015)

Source: CDC, 1991-2015

Source: CDC, 1991-2015

**Figure 3.9** Rates of Current Use of Cigarettes and Electronic Vapor Products in Indiana High School Students (9th -12th Grade), by Grade (Youth Risk Behavior Surveillance System, 2015)

Source: CDC, 1991-2015

#### **Indiana Youth Survey**

The Indiana Youth Survey, conducted annually of students in grades 6 to 12, assesses students' substance use, mental health, gambling, and risk and protective factors that can affect their academic success. Findings from the 2018 survey showed that tobacco use increased as students progressed in school, i.e., higher smoking rates occurred among 12th grade students than 8th graders, both for cigarettes and electronic vapor products (such as e-cigarettes, vaping pens, and e-hookahs) (see Figure 3.10) (Gassman et al., 2018). See Appendix 3B for Indiana students' 2018 monthly cigarette and vaping products use by region and grade.

**Figure 3.10** Monthly Cigarette Use and Vaping among 8th, 10th, and 12th Grade Students, Indiana and the United States (Indiana Youth Survey and Monitoring the Future Survey, 2018)

Source: Gassman et al., 2018; Inter-university Consortium for Political and Social Research, 2018

Comparisons between Indiana and the United States on 30-day prevalence of cigarette use and vaping among 12th grade students imply that (a) Hoosier students have had higher rates throughout the years, and (b) cigarette use has been declining, while vaping rates are at an all-time high (see Figure 3.11). However, these results need to be interpreted with caution, as statistical significance could not be determined due to the lack of detail provided in the publicly available data sets.

**Figure 3.11** Monthly Cigarette Use and Vaping among 12th Grade Students in Indiana and the United States (Indiana Youth Survey: 2008–2018; and Monitoring the Future Survey, 2008–2018)

Note: Vaping data only available since 2015.

Source: Gassman et al., 2018; Inter-university Consortium for Political and Social Research, 2018

#### Indiana College Substance Use Survey

The Indiana College Substance Use Survey includes questions on the use of various tobacco products. The 2018 survey, which was based on 24 participating colleges and universities, showed that electronic vapor products were the most commonly used nicotine delivery system, with 21.8% of Indiana college students reporting current (past-month) use (U.S.: 11.3%); followed by cigarettes, the second most common form (Indiana: 12.4%; U.S.: 8.0%). Consumption rates for the different types of tobacco/nicotine products by demographic characteristics can be found in Table 3.4 (King & Jun, 2018).<sup>1</sup>

#### CONSEQUENCES OF TOBACCO USE

The use of tobacco can lead to tobacco/nicotine dependence as well as tobacco-related diseases (CDC, 2017b). The risk of developing serious health problems associated with tobacco significantly decreases as people quit using tobacco products. Several factors influence tobacco cessation including healthcare coverage/costs, socioeconomic characteristics, availability of tobacco cessation products and media campaigns.

Additionally, tobacco use in K-12 students on school property or during school activities can lead to disciplinary actions, including suspensions and expulsions. During academic year 2018, a total of 4,817 suspensions/expulsions were recorded in Indiana schools involving tobacco use (Indiana Department of Education, 2019). For the number of tobacco-related incidents by county, see Appendix 3C.

#### **Tobacco-Related Morbidity**

Smoking affects respiratory health and is related to chronic coughing and wheezing among adults. Smokers are more likely than nonsmokers to have upper and lower respiratory tract infections. Generally, lung function deteriorates more quickly in smokers than in nonsmokers. Smoking contributes significantly to the number of deaths from lung cancer, heart disease, chronic lung diseases, and other illnesses (USDHHS, 2014). Adverse outcomes of smoking also include cancers of the oral cavity, pharynx, larynx, esophagus, bladder, stomach, cervix, kidney, and pancreas. Furthermore, smoking has been linked to liver, colorectal, prostate, and breast cancers, and can also result in acute myeloid leukemia (USDHHS, 2014). For smokingattributable cancers, the risk generally increases with the number of cigarettes smoked and the number of years of smoking, and usually decreases after the smoker quits completely. The leading cause of cancer deaths is lung cancer, and cigarette smoking causes most cases. However, any tobacco use can be detrimental. Smokeless tobacco has been shown to cause oral cancers and may also be a risk factor for cardiovascular disease (CDC, 2016a). Other specific health-related outcomes include age-related macular degeneration, dental disease, diabetes, autoimmune disease, rheumatoid arthritis, systemic lupus erythematosus, and inflammatory bowel disease (USDHHS, 2014).

Smoking may harm men's and women's reproductive health, and the effects can be seen in fetuses, infants, and children. Smoking can affect men's sperm and lead to reduced fertility and increased risk for

	Indiana (Total)	Male	Female	Under 21	21 or Over
Cigarettes	12.4	15.6	10.3*	10.8	15.1*
Cigars	6.8	12.3	3.6*	6.7	7.0
Chewing/smokeless tobacco	3.5	8.0	0.8*	3.3	3.9
Smoking tobacco with hookah/ water pipe	5.7	6.6	5.0*	5.0	6.8*
Electronic vapor products	21.8	28.2	17.9*	24.2	17.8

birth defects and miscarriage. Women who smoke have an increased risk for infertility and ectopic pregnancies. Smoking during pregnancy results in health problems for both mothers and babies. These include increased risk of spontaneous abortions, pregnancy complications (e.g., placenta previa, placental abruption, and premature rupture of membranes before labor begins), premature delivery, low birth-weight infants, stillbirth, and sudden infant death syndrome (SIDS). Mothers who smoke during pregnancy reduce their babies' lung function (CDC, 2016a). In Indiana, the percentage of births to mothers who smoked during pregnancy declined from 18.5% in 2007 to 13.5% in 2017; a higher percentage of white mothers (14.8%) smoked during pregnancy than black mothers (10.1%) in 2017 (ISDH/Epidemiology Resource Center, 2018). The Indiana State Department of Health, Tobacco Prevention and Cessation provides county-level information on various smoking-related outcomes. For a detailed list, see Appendix 3D.

Secondhand smoke: Secondhand smoke (sometimes called environmental tobacco smoke) has serious health consequences. An estimated 58 million nonsmoking Americans continue to be exposed to secondhand smoke in homes, vehicles, workplaces, and public places. Exposure to tobacco smoke can cause heart disease and lung cancer even in nonsmoking adults, increasing the risk by 25% to 30% for heart disease and by 20% to 30% for lung cancer. Children, in particular, are heavily impacted by secondhand smoke. Exposure increases their chance of developing significant lung conditions, especially asthma and bronchitis. Also, secondhand smoke can cause SIDS, acute respiratory infections, ear problems, and more frequent and severe asthma attacks in children. In the United States, secondhand smoke is responsible for nearly 34,000 deaths due to heart disease, more than 8,000 deaths from stroke, and over 7,300 lung cancer deaths each year among nonsmoking adults (USDHHS, 2014). An estimated 1,337 Hoosiers die each year from secondhand smoke (Lewis & Zollinger, 2014).

In Indiana, the percentage of smoke-free homes has increased from 60.1% in 2002 to 78.2% in 2017. The percentage of smoke-free workplaces<sup>2</sup> rose from 60.3% to 94.6% during that time period (see Figure 3.12). Although Indiana is making progress, it is lagging behind the rest of the nation terms of *comprehensive* coverage from secondhand smoke exposure (comprehensive coverage includes workplaces, restaurants, and bars). With the addition of the statewide smoke-free air law in 2012, all Indiana residents are covered in most workplaces and restaurants, but the law exempts bars, clubs, and gaming facilities. As of January 2019, a total of 23 communities<sup>3</sup> in Indiana have passed comprehensive smoke-free air ordinances which cover all workplaces, including bars, to ensure that all workers are protected from secondhand smoke. These 23 comprehensive ordinances cover approximately 31% of all residents in Indiana (ISDH/TPCC, 2019).

<sup>2</sup>This measure refers to the prevalence of workers reporting a 100% smoke-free workplace (Adult Tobacco Survey). <sup>3</sup>These are Delaware Co., Hancock Co., Howard Co., Monroe Co., Vanderburgh Co., Vigo Co., Austin, Bloomington, Columbus, Cumberland, Elkhart, Fort Wayne, Franklin, Greencastle, Indianapolis, Kokomo, Lawrence, North Manchester, Plainfield, South Bend, Terre Haute, West Lafayette, and Zionsville. **E-cigarettes:** Research shows that e-cigarette aerosol releases measurable amounts of carcinogens and other toxins into the air, including nicotine, formaldehyde, and acetaldehyde. In addition, e-cigarette aerosol has been found to contain a high concentration of ultra-fine particles. Exposure to fine and ultra-fine particles may exacerbate respiratory conditions and constrict arteries. In addition, nicotine from e-cigarettes may lead to increased heart rate and diastolic blood pressure. (ISDH/TPCC, 2018a).

E-cigarettes are the most commonly used tobacco product among youth in Indiana and nationwide. There is substantial evidence that e-cigarette use increases the risk of using regular combustible cigarettes among youth and young adults. For example, nearly half of Indiana high school students who used e-cigarettes in 2016 also smoked regular cigarettes, and the percentage of Hoosier adults reporting dual use was 58.5% (ISDH/ TPCC, 2018a).

In 2016, the U.S. Surgeon General issued a report highlighting concerns related to vaping among youth and young adults (USDHHS, 2016). Key findings of the report are as follows:

- E-cigarette use among youth and young adults has become a public health concern.
- E-cigarettes are the most commonly used tobacco product among youth, and use of e-cigarettes is strongly associated with use of other tobacco products.
- The use of products containing nicotine pose danger to youth, pregnant women, and fetuses. The use of products containing nicotine among youth, including e-cigarettes, is unsafe.
- E-cigarette aerosol is not harmless. It can contain harmful and potentially harmful constituents.
- E-cigarettes are marketed by promoting flavors and using a variety of media channels and approaches that have been used in the past to market tobacco to youth and young adults.

A new group of e-cigarette products look like USB drives. The most popular brand, JUUL (pronounced "jewel"), has grown quickly in popularity since introduction to the market in 2015, fueled by a large following among youth and young adults. Because of its unsuspecting appearance and small size, JUUL devices may not be immediately identified as an e-cigarette,

and can be easily concealed. The increased use of these products has become a concern for educators in Indiana. Many report that students are concealing JUUL and using it in schools. Nicotine use can have adverse effects on adolescent brain development. Therefore, nicotine use by youth in any form is unsafe, and efforts are warranted to educate youth about the dangers of use of all forms of tobacco products, regardless of whether they are combustible, noncombustible, or electronic. The skyrocketing e-cigarette use rate among youth observed in the past year has been partially attributed to the surge in JUUL popularity. The Surgeon General issued an advisory in December 2018 stressing the importance of protecting children from a lifetime of nicotine addiction and associated health risks by immediately addressing the epidemic of youth e-cigarette use.

#### **Tobacco-Related Mortality**

As the second major cause of death in the world, tobacco is responsible for approximately 6 million deaths every year, including about 600,000 deaths from exposure to secondhand smoke (World Health Organization, 2015). In the United States, cigarette smoking is the single most preventable cause of disease and death, causing more deaths annually than acquired immune deficiency syndrome (AIDS), alcohol, cocaine, heroin, homicide, suicide, motor vehicle crashes, and fires combined (USDHHS, 2014).

In the United States, tobacco use is responsible for more than 480,000 deaths per year among adults age 35 and older. In addition, 16 million adults are suffering from smoking-related conditions. On average, smoking reduces adult life expectancy by a minimum of 10 years. Smoking is the leading risk-factor for lung cancer, which is the foremost cause of cancer-related deaths for both males and females (Siegel, Miller, & Jemal, 2015).

#### **Economic Impact**

In 2016, the annual U.S. tobacco industry marketing expenditures were approximately \$9.5 billion, including Indiana's share of \$296.8 million. The state's total tobacco marketing expenditures declined after peaking at \$475.4 million in 2003 (Campaign for Tobacco-Free Kids, 2018b; Federal Trade Commission, 2018).

The federal excise tax is \$1.01 per pack of cigarettes. The average state cigarette excise tax is \$1.79 per pack, but varies from 17 cents in Missouri to

\$4.50 in Washington DC; Indiana's tobacco excise tax rate is 99.5 cents per pack (Campaign for Tobacco-Free Kids, 2018a).

Cigarette smoking is estimated to be responsible for greater than \$300 billion in annual health-related economic losses in the United States (\$170 billion in direct medical costs and approximately \$156 billion in lost productivity) (CDC, 2016a). In Indiana, \$2.93 billion dollars of health-related costs in 2009 were smoking-attributable expenditures (SAE). Most of these costs accrued through hospital care (\$1.57 billion) and prescription drugs (\$525 million); the SAE estimate also included ambulatory care (\$405 million), nursing home care (\$283 million), and other health-related costs (\$147 million) (CDC, 2016a). The combination of increased medical costs, higher insurance rates, added maintenance expenses, lower productivity, and higher rates of absenteeism due to smoking adds financial strain to U.S. businesses every year.

#### **APPENDIX 3A**

Percentage of Indiana Middle School and High School Students Who Currently Use Cigarettes, E-Cigarettes, or Smokeless Tobacco by Gender, Race/Ethnicity, and School Grade (Indiana Youth Tobacco Survey, 2016)

# MARIJUANA USE IN INDIANA: CONSUMPTION PATTERNS AND CONSEQUENCES

#### INTRODUCTION

Marijuana is a product of the hemp plant, known as Cannabis sativa. Found in the dried leaves, stems, seeds, and flowers, delta-9-tetrahydrocannabinol (THC) is the primary psychoactive (mind-altering) chemical. The drug can be consumed in different ways: by smoking "joints" or "blunts" (hand-rolled cigarettes or cigars filled only with cannabis, not tobacco) and hookahs (water pipes), mixing into foods, or brewing as tea (Hall & Solowij, 1998). Recent studies show an increase in edible consumption of marijuana, especially in states that allow medical use of marijuana (National Institute on Drug Abuse [NIDA], 2016a). Marijuana is the most commonly used illicit drug in the United States (Azofeifa et al., 2016).

Age of first use is an important risk factor in the subsequent progression to substance misuse and dependence (King & Chassin, 2007). Adolescents who used marijuana by the age of 17 were found to be at greater risk of using other drugs and developing alcohol and drug abuse/dependence (Lynskey et al., 2003). The use of marijuana can result in adverse physical, mental, emotional, and behavioral changes. Short-term effects include memory impairment and learning problems, distorted perception, difficulty thinking and solving problems, loss of coordination, and increased heart rate. Long-term use has been linked to respiratory illnesses

and an increased risk of heart attack and cancer (Crean, Crane, & Mason, 2011; Volkow, Baler, Compton, & Weiss, 2014). Furthermore, prolonged marijuana use can lead to mental health problems such as depression, anxiety, suicidal thoughts, and personality disturbances (Patton et al., 2002; Caspi et al., 2005).

Babies born to women who used marijuana during their pregnancy may be at an increased risk for neurobehavioral problems, potentially exhibiting difficulties with attention, memory, and problem solving (NIDA, 2016a).

## PREVALENCE OF MARIJUANA CONSUMPTION IN THE GENERAL POPULATION

#### National Survey on Drug Use and Health

According to the 2017 National Survey on Drug Use and Health (NSDUH), an estimated 9.3% (95% Confidence Interval [CI]: 8.0–10.8) of Indiana residents ages 12 and older reported current (past-month) marijuana use (U.S.: 9.2%; 95% CI: 9.0–9.5); past-year use was estimated at 14.4% (95% CI: 12.8–16.2; U.S.: 14.5%; 95% CI: 14.2–14.8) (Substance Abuse and Mental Health Services Administration [SAMHSA], 2017). For 10-year trend data on past-month marijuana use, see Figure 4.1.

Source: SAMHSA, 2017

The highest prevalence was among individuals ages 18 to 25, with 20.7% (95% CI: 17.6–24.2) of Hoosiers in this age group reporting current marijuana use (U.S.: 21.5%; 95% CI: 20.8–22.1) and 33.9% (95% CI: 30.1–37.8) reporting past-year use (U.S.: 33.9%; 95% CI: 33.3–34.7) in 2017 (Figure 4.2). Prevalence rates were significantly lower in youth and adults ages 26 and older. Based on 2017 estimates, 13.3% (95% CI: 11.1–15.9) of 12- to 17-year-olds in Indiana reported using marijuana

in the past year (U.S.: 12.2%; 95% CI: 11.8–12.6) and 6.5% (95% CI: 5.2–8.1) in the past month (U.S.: 6.5%; 95% CI: 6.1–6.8). Among Hoosiers ages 26 and older, 7.7% (95% CI: 6.2–9.4) reported past-month marijuana use (U.S.: 7.6%; 95% CI: 7.3–7.8) and 11.2% (95% CI: 9.5–13.2) reported use in the past year (U.S.: 11.6%; 95% CI: 11.3–12.0) (SAMSHA, 2017). See Figure 4.2 for current marijuana use rates by age group in Indiana.

**Figure 4.2** Percentage of Indiana Residents Reporting Current Marijuana Use, by Age Group (National Survey on Drug Use and Health, 2008–2017)

Source: SAMHSA, 2017

Marijuana initiation, or first-time use, was primarily reported in young adults and adolescents. An estimated 8.8% (95% CI: 7.1–11.0) of Hoosiers ages 18 to 25 initiated marijuana use in the past year (U.S.: 8.0%; 95% CI: 7.6–8.4), as did 6.0% (95% CI: 5.0–7.3 of Indiana youth ages 12 to 17 (U.S.: 5.2%; 95% CI: 5.0–5.5). Past-year initiation was significantly lower in adults ages 26 and older (IN: 0.5%; 95% CI: 0.4–0.7; U.S.: 0.5%; 95% CI: 0.4–0.5) (SAMHSA, 2017).

#### Youth Risk Behavior Surveillance System

The Youth Risk Behavior Surveillance System (YRBSS) estimated that in 2015, 16.4% (95% CI: 14.1–18.9) of Indiana high school students used marijuana in the past month; this percentage is significantly lower than the national rate of 21.7% (95% CI: 19.3–24.2). Use was more likely to occur in higher grade levels and in black or Hispanic students (Centers for Disease Control and Prevention [CDC], 1999-2015). For more detailed information, see Table 4.1 and Figure 4.3.

Note: 2013 estimates are not available for Indiana. Source: CDC, 1999-2015

Table 4.1Percentage of Indiana and U.S. High SchoolStudents Reporting Current (Past Month) MarijuanaUse, by Grade, Gender, and Race/Ethnicity (Youth RiskBehavior Surveillance System, 2015)

		Indiana (95% CI)	U.S. (95% CI)
Grade	9th	13.7% (10.4–17.9)	15.2% (16.8–23.5)
	10th	16.8% (12.5–22.2)	20.0% (24.0–30.4)
	11th	17.0% (13.2–21.7)	24.8% (22.3–27.5)
	12th	18.4% (14.1–23.7)	27.6% (23.8–31.6)
Gender	Male	16.4% (13.8–19.4)	23.2% (20.4–26.3)
	Female	15.9% (12.7–19.7)	20.1% (17.6–22.9)
Race/Ethnicity	Black	23.2% (17.1–30.7)	28.9% (26.3–31.6)
	White	14.9% (12.4–17.8)	20.4% (17.8–23.3)
	Hispanic	18.1% (13.6–23.6)	27.6% (24.6–30.7)
Total		16.4% (14.1–18.9)	21.7% (19.3–24.2)

Source: CDC, 2017

In 2015, 6.2% (95% CI: 5.3–7.4) of Indiana students reported having tried marijuana before the age of 13; that figure was comparable to the national rate (7.5%; 95% CI: 6.5–8.7) (CDC, 1999-2015).

#### Indiana Youth Survey

Data from the Indiana Youth Survey (Gassman et al., 2018), and the Monitoring the Future (MTF) survey (Inter-university Consortium for Political and Social Research [ICPSR], 2018) show that marijuana use among 8th, 10th, and 12th grade students increased with grade level/age. Prevalence rates for current marijuana use in Indiana and the nation were similar; however, due to lack of detail in the publicly available dataset, statistical significance could not be determined. For current marijuana use trends among 8th, 10th, and 12th grade students from 2009 through 2018, see Figure 4.4; for monthly marijuana use by Indiana region and grade level for 2018, see Appendix 4A.

#### Indiana College Substance Use Survey

Marijuana use was also prevalent among college students. Results from the 2018 Indiana College Substance Use Survey showed that 22.7% of Indiana college students reported current marijuana use (U.S.: 21.2%). Users were more likely to be male and between the ages of 21 and 25 (King & Jun, 2018).<sup>1</sup>

# USE OF MARIJUANA IN THE TREATMENT POPULATION

#### **Treatment Episode Data Set**

The Treatment Episode Data Set (TEDS) collects information from clients being admitted to substance abuse treatment. The data show that from 2007 through 2016, Indiana exhibited a significantly higher percentage of treatment episodes reporting marijuana use and dependence<sup>2</sup> compared to the rest of the United States. From 2007 through 2016, roughly one-half of Indiana treatment admissions reported marijuana use and about one-fifth indicated marijuana dependence (see Figure 4.5) (SAMHSA, 2016).

**Figure 4.5** Percentage of Indiana and U.S. Treatment Episodes with Marijuana Use and Marijuana Dependence Reported at Treatment Admission (Treatment Episode Data Set, 2007–2016)

Source: SAMHSA, 2016

<sup>1</sup>Twenty-four Indiana colleges participated in the survey; results are based on nonrandom sampling and are not representative of all college students in Indiana.

<sup>2</sup>We defined marijuana dependence as "individuals in substance abuse treatment listing marijuana as their primary substance at admission."

Table 4.2Percentage of Indiana Treatment Admissionswith Reported Marijuana Use, by Gender, Race, and AgeGroup (Treatment Episode Data Set, 2016)

		Marijuana Use
Gender	Male	51.5%
	Female	43.7%
Race	White	46.6%
	Black	57.4%
	Other	52.7%
Age Group	Under 18	89.9%
	18-24	66.4%
	25-34	48.9%
	35-44	41.7%
	45-54	32.9%
	55+	24.8%
Total		48.4%

Statistically significant differences in marijuana use among Indiana's treatment population were observed by gender, race, and age, as follows:

- The percentage of males reporting marijuana use was higher than the percentage of females.
- The percentage of Blacks who reported marijuana use was higher compared to Whites and other races.
- Marijuana use decreased by age; i.e., the highest percentage was found among adolescents under the age of 18 and the lowest among older adults ages 55 and above (see Table 4.2).

For county-level information on marijuana use and dependence, see Appendix 4B (Indiana Family and Social Services Administration, 2018).

Source: SAMHSA, 2016

#### CONSEQUENCES OF MARIJUANA USE

The debate around the potential harms and benefits of marijuana use is perhaps the most fervent it has ever been as numerous states have or are in the process of implementing medical and recreational marijuana legislation. As of December 2018, 33 states and the District of Columbia (D.C.) have legalized medical marijuana use, and 10 of these states, as well as D.C., have passed laws to allow adult recreational use (National Conference of State Legislatures, 2018). Existing research shows that marijuana use is associated with numerous deleterious health effects. Short-term use is associated with impaired motor coordination and altered judgement that can increase the likelihood of other risky behaviors. Long-term use can increase the risk of mental illness, use of other substances, and chronic bronchitis (Volkow et al., 2014).

Persistent cannabis use is associated with decreased functional connectivity in the brain, IQ decline, and increased memory and attention issues (Meier et al., 2012; Zalesky et al., 2012). In addition to the aforementioned negative health effects, cannabis dependence can have undesirable economic and social implications. A longitudinal study found that regular users of cannabis were more likely to end up in a lower social class than their parents, have more relationship and workplace problems, and experience more financial difficulties in early midlife (Cerdá et al., 2016). Conversely, medical marijuana use has been shown to relieve the symptoms of numerous clinical conditions including glaucoma, nausea, chronic pain, inflammation, disease-induced decreased appetite, multiple sclerosis, and epilepsy (Volkow et al., 2014).

#### **APPENDIX 4A**

Percentage of Indiana Students Reporting Monthly Marijuana Use, by Region and Grade (Indiana Youth Survey, 2018)

	Indiana	Northwest	North Central	Northeast	West	Central	East	Southwest	Southeast

# **OPIOID USE IN INDIANA: CONSUMPTION PATTERNS AND CONSEQUENCES**

#### INTRODUCTION

Opioids are a class of drugs that are used to reduce pain. They include legal substances such as prescription pain relievers received from a physician and illegal substances such as heroin or illicitly manufactured fentanyl. All opioids are chemically similar and the brain does not distinguish between legal and illegal opioids. By binding to special opioid receptors on nerve cells in the brain and body, opioids block pain signals and are responsible for the release of large amounts of dopamine. The release of dopamine has a strong reinforcing effect and is often experienced as "euphoria" and a "sense of wellbeing" in users (National Institute on Drug Abuse [NIDA], 2016, 2018a, 2018b).

Common prescription opioids include oxycodone (e.g., OxyContin®, Percocet®), hydrocodone (e.g., Vicodin®), oxymorphone (e.g., Opana ®), codeine, morphine, and fentanyl (NIDA, 2018b). Fentanyl is a powerful synthetic opioid similar to morphine but 50 to 100 times stronger. The high potency of the drug significantly increases its risk for overdose. Fentanyl is typically used to treat severe pain or to manage pain after surgery. However, non-pharmaceutical fentanyl is sold on the streets in form of a powder, spiked on blotter paper, and mixed with heroin or other drugs (NIDA, 2016). Prescription opioids are generally safe when taken for a short time and as prescribed by a healthcare provider. However, regular use, even as prescribed, can lead to dependence and addiction, and may result in overdose (NIDA, 2018b).

Heroin is a semi-synthetic illegal drug derived from morphine, a naturally occurring substance extracted from the opium poppy. Heroin is available in the form of a white or brown powder, or a black sticky substance commonly known as black tar heroin (NIDA, 2018a).

#### **INSPECT**

INSPECT is Indiana's prescription drug monitoring program; it collects information on all controlled substances (DEA Schedules II through V) dispensed within the state. In 2018, nearly 5.7 million prescriptions for opioids were filled in Indiana, reflecting a dispensation rate of 214.3 per 1,000 residents. The number and rate of opioid dispensations has been gradually declining for the past two years (see Figure 5.1) (Indiana State Department of Health [ISDH], 2019). For county-level information see Map 5.1 and Appendix 5A.

Figure 5.1 Number and Rate (per 1,000 Population) of Opioids Dispensed in Indiana per Quarter (INSPECT, 2017-

Note: Dispensation data includes three opioid prescription categories: (1) opioid analgesics, (2) opioid antidiarrheals/ antitussives, and (3) opioid antagonists and treatment addiction medications. Source: ISDH, 2019

#### Center for Health Policy

#### PREVALENCE OF OPIOID CONSUMPTION IN THE GENERAL POPULATION National Survey on Drug Use and Health

Based on 2016–2017 averages from the Substance Abuse and Mental Health Services Administration (SAMHSA)'s National Survey on Drug Use and Health (NSDUH), an estimated 4.8% (95% Confidence Interval [CI]: 4.1–5.7) of Indiana residents ages 12 and older misused pain relievers in the past year (U.S.: 4.2%; 95% CI: 4.0–4.3). The highest rate was found among young adults ages 18 to 25, at 8.8% (95% CI: 7.1–10.9); this represents a rate statistically similar to the nation's rate of 7.1% (95% CI: 6.8–7.5) (SAMHSA, 2017). For additional rates by age group, see Figure 5.2.

(In 2015, SAMHSA redesigned the questions in the NSDUH pertaining to the use and misuse of prescription drugs. Due to these changes, new estimates cannot be compared to previous years of the NSDUH.)

**Figure 5.2** Prevalence of Past-Year Pain Reliever Use in Indiana and the United States, by Age Group (National Survey on Drug Use and Health, 2016-2017)

Source: SAMHSA, 2017

Although heroin use in the general U.S. population is relatively low (an estimated 0.3%), the percentage of Americans using the drug is higher than it was 10 years ago (Lipari and Hughes, 2015). Heroin has also become a major concern in Indiana. Its rise in use, as evidenced by the increase in heroin overdose fatalities, has led to several efforts by state agencies and organizations to identify and develop sources of Indiana-specific data and surveillance (Indiana State Department of Health [ISDH], 2019). According to findings from the 2016–2017 NSDUH, 0.6% (95% CI: 0.4–1.1) of Hoosiers ages 12 and older reported using heroin in the past year; the U.S. rate was similar. Past-year heroin use was most prevalent among young adults ages 18 to 25, at 1.3% (95% CI: 0.7–2.3) (SAMHSA, 2017). For additional rates by age group, see Figure 5.3.

**Figure 5.3** Percentage of Indiana and U.S. Population (12 years and older) Reporting Past-Year Heroin Use, by Age Group (National Survey on Drug Use and Health, 2016-2017)

Source: SAMHSA, 2017
#### Youth Risk Behavior Surveillance System

In 2015, 2.4% (95% CI: 1.3–4.4) of high school students (grades 9 through 12) in Indiana reported having tried heroin at least once in their life, according to the 2015 Youth Risk Behavior Surveillance System (YRBSS). Indiana's rate was similar to the national rate of 2.1%

(95% CI: 1.5–2.8) (see Figure 5.4). No statistical differences by gender, race, or grade level were observed in 2015. Prevalence of lifetime heroin use has remained relatively stable among both Indiana and national high school students from 2005 through 2015 (Centers for Disease Control and Prevention [CDC], 1991–2015).

Note: 2013 estimates for Indiana are not available. Source: CDC, 1991–2015

As noted previously, a common route of administration for heroin is by needle injection. According to the 2015 YRBSS, the percentage of high school students who used a needle to inject any illegal drug into their body one or more times during their lifetime was statistically similar in Indiana (2.2%; 95% CI: 1.1–4.3) and the nation (1.8%; 95% CI: 1.3–2.3) (CDC, 1991– 2015).

(While the YRBSS offers information on overall prescription drug misuse, it does not provide estimates for prescription pain reliever misuse specifically.)

#### Indiana Youth Survey

Based on results from the 2018 Indiana Youth Survey (INYS), past-month heroin use among 7th through 12th grade students was between 0.0% and 0.2% (see Figure 5.5). Heroin use among Indiana 12th graders peaked in 2011 at 1.2%, but is now at 0.2% (see Figure 5.6) (Gassman et al., 2018). For monthly heroin use rates in Indiana by region and grade level, see Appendix 5B.

**Figure 5.5** Percentage of Indiana 7th through 12th Grade Students Reporting Monthly Heroin Use (Indiana Youth Survey, 2018)

Source: Gassman et al., 2018

**Figure 5.6** Percentage of Indiana and U.S. 12th Grade Students Reporting Monthly Heroin Use (Indiana Youth Survey and Monitoring the Future Survey, 2009–2018)

Source: Gassman et al., 2018; Inter-university Consortium for Political and Social Research, University of Michigan, 2018

#### Indiana College Substance Use Survey

The Indiana College Substance Use Survey<sup>1</sup> includes questions on the past-month use of opioids and prescription painkillers not prescribed to the student. Findings from the 2018 survey were as follows:

a) Misuse of prescription painkillers:

- 1.7% of Indiana college students misused prescription painkillers in the past month.
- Rates did not differ significantly by gender.
- Rates were higher among college students ages 21 to 25 (2.0%) compared to those under the age of 21 (1.5%).
- b) Misuse of heroin:
  - 0.2% of Indiana college students reported using heroin within the past month.
  - Rates did not differ significantly by gender or age group.

(King & Jun, 2018).

#### USE OF OPIOIDS IN THE TREATMENT POPULATION Treatment Episode Data Set

Another method of tracking opioid misuse is to examine the Treatment Episode Data Set (TEDS) for individuals who report misuse of prescription pain relievers<sup>2</sup> or heroin at the time of substance use treatment admission.

In nearly 21% of Indiana treatment admissions, misuse of prescription opioids was reported (U.S.: 13.9%) and in over 10%, dependence<sup>3</sup> was indicated in 2016 (SAMHSA, 2016). Significant differences in self-reported prescription opioid misuse were seen by gender, race, and age group. Generally speaking, women, whites, and adults between the ages of 25 and 44 had the highest percentages of misuse and dependence (see Table 5.1). Furthermore, the percentage of treatment admissions attributable to prescription opioids has increased from 2007 to 2016, with a peak in any prescription opioid misuse reported at admission in Indiana in 2014 (see Figure 5.7). For county-level information, see Appendix 5C.

**Table 5.1**Percentage of Indiana and U.S. Treatment Episodes with Prescription Opioid Misuse and DependenceReported at Treatment Admission, by Gender, Race, and Age Group (Treatment Episode Data Set, 2016)

				1	
		Mi	suse	Depe	ndence
		Indiana	U.S.	Indiana	U.S.
Gender	Male	17.6%	11.5%	8.5%	6.4%
	Female	25.9%	17.8%	13.1%	10.7%
Race	White	23.7%	17.1%	11.7%	9.7%
	Black	6.0%	5.9%	3.0%	3.3%
	Other	15.9%	8.9%	8.2%	4.7%

Source: SAMHSA, 2016

<sup>2</sup>We used TEDS variables "nonprescription methadone" and "other opiates/synthetics" to define pain reliever use (excludes heroin). <sup>3</sup>We defined prescription pain reliever dependence as "individuals in substance abuse treatment listing prescription pain relievers as their primary substance at admission."

<sup>&</sup>lt;sup>1</sup>Twenty-four (24) colleges participated in the 2018 survey; results are based on nonrandom sampling and are not representative of all college students in Indiana.

**Figure 5.7** Percentage of Indiana and U.S. Treatment Episodes with Prescription Opioid Misuse and Dependence Reported at Treatment Admission (Treatment Episode Data Set, 2007–2016)

Source: SAMHSA, 2016

In over one-fifth of Indiana treatment admissions in 2016, heroin use was reported; heroin dependence<sup>4</sup> was indicated in 17.5% of admissions (SAMHSA, 2016). Though the percentage of treatment admissions

attributable to heroin in Indiana increased significantly from 2007 through 2016, Indiana's percentage remained below the U.S. percentage. For additional trend information, see Figure 5.8.

**Figure 5.8** Percentage of Indiana and U.S. Treatment Episodes with Heroin Use and Dependence Reported at Treatment Admission (Treatment Episode Data Set, 2007–2016)

Source: SAMHSA, 2016

<sup>4</sup>We defined heroin dependence as "individuals in substance abuse treatment listing heroin as their primary substance at admission."

Within Indiana's treatment population, reported heroin use and dependence differed significantly by gender, race, and age group:

- Gender—Reported heroin use and dependence increased among both males and females, but has consistently been higher in females.
- Race—Whites had the highest percentage of heroin use and dependence compared to all other races.
- Age—Heroin use and dependence within Indiana's treatment population was highest among adults ages 25 to 34.

For additional details, see Table 5.2 (SAMHSA, 2016); for county-level information, see Appendix 5C.

#### **Opioid Treatment Programs**

Opioid treatment programs (OTPs) provide medicationassisted treatment to individuals with an opioid use disorder. OTPs are certified by SAMHSA, accredited by an independent SAMHSA-approved accrediting body, and licensed by the state in which they operate. Federal law requires OTPs to provide medical, counseling, vocational, educational, and other assessment and treatment services, in addition to prescribed medication. In 2017, a total of 13,697 unique patients were treated in OTPs in Indiana (Indiana Family and Social Services Administration, 2018b).

#### CONSEQUENCES OF OPIOID USE Fatal and Non-Fatal Drug Overdoses

In high doses and/or combined with alcohol and certain other drugs, opioids can cause respiratory depression and lead to death (NIDA, 2018a). Drug overdose deaths (from all drugs) increased in Indiana from 9.7 per 100,000 population (U.S.: 10.1) in 2005 to 29.4 per 100,000 population (U.S.: 21.7) in 2017 (CDC, 1999– 2017).<sup>5</sup> A large percentage of overall drug overdoses involve opioids. In Indiana, the number of overdose deaths involving an opioid rose from 347 in 2011 to 1,138 in 2017 (ISDH, 2019). For 2011 through 2017 overdose mortality rates involving opioids, see Figure 5.9.

In addition, a total of 8,169 visits to Indiana emergency departments occurred due to a nonfatal opioid overdose in 2017 (ISDH, 2019).

<sup>5</sup>Includes ICD-10 causes of death: X40-X44, X60-X64, X85, Y10-Y14.

Figure 5.9 Drug Overdose Deaths Involving Opioids, Rate per 100,000 Population (Indiana, 2011–2017)

Note: "Rx (prescription) Opioid" and "Heroin" are subcategories of "Any Opioid". Overdose deaths involving prescription opioids or heroin are not mutually exclusive as multiple drugs are frequently involved in overdose deaths. Source: ISDH, 2019

#### HIV/AIDS and Hepatitis B & C

Opioids, especially when injected, are a significant risk factor for contracting human immunodeficiency virus infection (HIV) and hepatitis B and C, due to the common practice of needle-sharing among injection drug users (NIDA, 2018c). However, drug use in any form is associated with risk behaviors related to infectious disease transmission (NIDA, 2018c).

As of December 31, 2017, a total of 12,635 individuals in Indiana were living with HIV or AIDS, representing an annual HIV/AIDS prevalence rate of 190.5 per 100,000 population. In 2017, there were 547 new cases of HIV/AIDS. In nearly 9% of these new cases, injection drug use (IDU) was reported, either as the sole risk factor for contracting HIV/AIDS or in combination with other risk factors (ISDH, 2019).

Indiana's age-adjusted HIV/AIDS mortality rate for 2016 was 1.0 per 100,000 population (95% CI: 0.8–1.3), which was similar to the U.S. rate of 1.6 per 100,000 population (95% CI: 1.6–1.6) (CDC, 1999–2017).<sup>6</sup>

Hepatitis is a liver disease that is caused by viral infection. The hepatitis B virus (HBV) and hepatitis C virus (HCV) are transmitted when blood of an infected person enters the body of a person who is not infected. Injection drug use (IDU) is a major risk factor for both acquiring and transmitting HBV and HCV. It is estimated that each injection drug user infected with HCV is likely to infect 20 other people, extending the risk of infection far beyond the individual using the drug (NIDA, 2018d).

In 2017, there were 905 cases of hepatitis B (including 170 acute and 735 chronic cases) and 8,222 cases of hepatitis C (including 236 acute and 7,986 chronic cases) in Indiana (ISDH, 2019).

The 2017 age-adjusted mortality rate attributable to HBV and HCV<sup>7</sup> combined was 1.0 per 100,000 population (95% CI: 0.8–1.2) in Indiana, which was below the national rate of 1.3 per 100,000 population (95% CI: 1.3–1.4) (CDC, 1999–2017).

<sup>6</sup>Mortality rates for HIV/AIDS are based on ICD-10 codes B20-B24 (Human immunodeficiency virus [HIV] disease). <sup>7</sup>Mortality rates for hepatitis B and C infections are based on the following ICD-10 codes: B16 (Acute hepatitis B), B17.0 (Acute delta-[super]infection of hepatitis B carrier), B17.1 (Acute hepatitis C), B18.0 (Chronic viral hepatitis B with delta-agent), B18.1 (Chronic viral hepatitis B without delta-agent), B18.2 (Chronic viral hepatitis C).

### **Pharmacy Robberies**

The number of pharmacy robberies in Indiana peaked in 2015 with 175 robberies, but decreased to 22 robberies in 2017. These 22 robberies were responsible

for nearly 37,000 doses of stolen controlled substances, reflecting a purchase value of \$76,439 (see Table 5.3) (IPLA, 2018).

٦	Table 5.3	Pharmacy	Robberies	in Indiana	(Sum	mary Report)

	2013	2014	2015	2016	2017
Number of Robberies	71	80	175	75	22
Purchase Value of Stolen Drugs	\$202,133	\$293,079	\$479,785	\$246,138	\$76,439

#### **APPENDIX 5C** (Continued from previous page)

Notes: We defined prescription opioid dependence as "individuals in substance abuse treatment listing prescription opioids as their primary substance at admission."

We defined heroin dependence as "individuals in substance abuse treatment listing heroin as their primary substance at admission."

We calculated the percentages by dividing the number of reported prescription drug use/dependence by the number of treatment episodes.

Information on treatment episodes <5 was suppressed due to confidentiality constraints.

## STIMULANT USE IN INDIANA: CONSUMPTION PATTERNS AND CONSEQUENCES

#### INTRODUCTION

Stimulants encompass a group of both legal and illicit drugs that share similar physiological mechanisms of action. When ingested, stimulants lead to an increase in alertness, attention, and energy while also elevating blood pressure, heart rate, and respiration. In the brain, stimulants raise dopamine levels which can lead to feelings ranging from pleasure to intense euphoria. Stimulant use is also often associated with feelings of increased wakefulness, motivation, mental focus, and libido (National Institute on Drug Abuse [NIDA], 2018). While a number of stimulant drugs exist, the three associated with the greatest level of problematic use are cocaine, methamphetamine, and prescription stimulants.

Cocaine is a highly addictive stimulant produced from the leaves of the coca plant. The two most common forms of cocaine are powder cocaine and crack cocaine. Powder cocaine is a fine white powder and, while it can be injected, is most often snorted or inhaled. Crack cocaine is cocaine that has been processed into a rock crystal. Crack is typically used by placing the crystals into a glass pipe, heating them, and then inhaling the vapors. The name "crack" refers to the crackling sound made when the rock is heated (NIDA, 2016a, 2016b). Both forms of cocaine increase levels of dopamine in the brain resulting in a short-lived, intense high that can range from 15 to 30 minutes for powder cocaine or 5 to 10 minutes for crack cocaine.

Methamphetamine (meth), also known as "crystal" or "ice", is a highly addictive stimulant derived from amphetamine. Although meth can be taken in a variety of ways, most users in Indiana report either smoking it or injecting it intravenously (Indiana Family and Social Services Administration [FSSA], 2017; NIDA, 2017). Upon initial administration, meth users experience a short, intense euphoria or "rush" followed by an extended high that can last up to 12 hours due to the drug's long half-life (Halkitis, Parsons, & Stirrat, 2001; Centers for Disease Control and Prevention [CDC], 2007). The intensity of meth stimulation depends on the mode of administration. Oral ingestion or snorting produces a longer-lasting, but less intense effect, while smoking or injecting results in a briefer but more intense rush (Homer et al., 2008).

Prescription stimulants are legally produced stimulants such as dextroamphetamine (Dexedrine), methylphenidate (Ritalin), amphetamine sulfate (Adderall), and lisdexamfetamine (Vyvanse). These drugs increase alertness, attention, and energy and are used for the treatment of narcolepsy and attentiondeficit hyperactivity disorder. Although some people may choose to use prescription stimulants as a way to get high, many individuals who use these drugs inappropriately may do so in an attempt to enhance academic/work performance or improve memory (NIDA, 2018).

#### PREVALENCE OF STIMULANT CONSUMPTION IN THE GENERAL POPULATION National Survey on Drug Use and Health

The National Survey on Drug Use and Health (NSDUH) estimated that in 2017, approximately 1.9% (95% Confidence Interval [CI]: 1.4–2.5) of Hoosiers 12 years of age or older used cocaine in the past year, an estimate similar to that for the nation (2.0%; 95% CI: 1.9–2.1). Across age groups, cocaine use was highest among persons between the ages of 18 and 25 in both Indiana (5.7%, 95% CI: 4.2-7.8) and the U.S. (5.9%, 95% CI: 5.5-6.3) (see Figure 6.1). Over the last 10 years, the rate of past-year cocaine use in both Indiana and the U.S. has remained fairly stable (see Figure 6.2) (Substance Abuse and Mental Health Services Administration [SAMHSA], 2017).

**Figure 6.2** Percentage of Indiana and U.S. Population (12 Years and Older) Reporting Cocaine Use in the Past Year (National Survey on Drug Use and Health, 2008-2017)

Source: SAMHSA, 2017

2017 is the first year in which state-level NSDUH estimates on methamphetamine use were available. In Indiana, 0.6% of Hoosiers (95% CI: 0.4-1.0) reported using meth in the past year; the U.S. rate was the same (0.6%; 95% CI: 0.5-0.6). For prevalence rates by age group, see Figure 6.3 (SAMHSA, 2017).

#### Youth Risk Behavior Surveillance Survey

According to the 2015 Youth Risk Behavior Surveillance System (YRBSS), 4.0% (95% CI: 2.9–5.7) of Indiana high school students (grades 9-12) reported that they had used a form of cocaine at least once in their lifetime. National rates for lifetime use were similar, at 5.2% (95% CI: 4.3–6.2). The difference in Indiana prevalence rates by gender, race/ethnicity, or grade level was not statically significant (see Table 6.1) (CDC, 1991-2015). The YRBSS estimated that in 2015, 2.9% (95% CI: 1.5–5.4) of Indiana high school students and a similar percentage of U.S. high school students (3.0%; 95% CI: 2.4–3.8) had ever used meth. Since 2003, the percentage of Indiana's high school students estimated to have used either cocaine or meth has gradually declined (see Figure 6.4). The YRBSS does not ask students to describe their use of prescription stimulants.

**Table 6.1** Percentage of Indiana and U.S. High School Students (Grades 9 through 12) Reporting Lifetime Cocaine or Methamphetamine Use, by Gender, Race/Ethnicity, and Grade (Youth Risk Behavior Surveillance System, 2015)

		С	ocaine	Metham	phetamine
		Indiana (95%)	U.S. (95%)	Indiana	U.S.
Gender	Male	5.2% (3.4–7.9)	6.3% (5.1–7.9)	4.1% (2.0-8.2)	3.6% (2.6–4.9)
	Female	2.7% (1.7–4.2)	3.8% (3.1–4.6)	1.4% (0.8–2.6)	2.3% (1.7–3.0)
Race/Ethnicity	White	3.6% (2.3–5.6)	4.1% (3.3–5.2)	2.4% (1.1–5.3)	2.1% (1.5–2.8)
	Black	3.7% (1.2–10.7)	3.8% (2.5–6.0)	3.7% (1.2–10.7)	2.8% (1.5–5.1)
	Hispanic	7.9% (4.2–14.1)	8.0% (6.6–9.7)	3.2% (1.4–7.0)	4.4% (3.3–5.9)
Grade	9	3.5% (1.6–7.2)	3.4% (2.6–4.5)	3.5% (1.6–7.8)	2.0% (1.5–2.7)
	10	4.7% (3.4–6.5)	5.1% (3.8–6.8)	2.3% (1.4–3.8)	3.3% (2.3–4.9)
	11	4.7% (2.6–8.6)	5.0% (3.9–6.5)	3.7% (1.5–8.9)	2.8% (1.9–4.0)
	12	3.4% (1.8–6.3)	7.2% (5.6–9.1)	1.6% (0.4–6.6)	3.8% (2.7–5.3)
Total		4.0% (2.9–5.7)	5.2% (4.3–6.2)	2.9% (1.5–5.4)	3.0% (2.4–3.8)

# Indiana Youth Survey and Monitoring the Future Survey

Both the Indiana Youth Survey (INYS) and the Monitoring the Future survey (MTF) provide local and national estimates, respectively, of current cocaine and methamphetamine use among 8th, 10th, and 12th grade students. Neither survey asks students to report on their current inappropriate use of prescription stimulants. According to the 2018 INYS, only a small percentage of Indiana's 8th, 10th, and 12th graders reported currently using either cocaine or meth. Current use of both substances has been decreasing in Indiana over the past 10 years and these decreases are consistent with national trends (see Figures 6.5 and 6.6) (Gassman et al., 2018; Inter-university Consortium for Political and Social Research [ICPSR], 2018). For 2018 data on current cocaine/crack use and meth use among students in grades 7 through 12 by Indiana region, see Appendix 6A.

#### The Indiana College Substance Use Survey

The Indiana College Substance Use Survey (ICSUS) provides estimates of alcohol, tobacco, and other drug use among Indiana college students. According to findings from the 2018 survey, which were based on 24 participating colleges and universities:

- 2.9% of Indiana college students reported having used cocaine in the past month,
- · 0.2% reported having used meth, and
- 5.3% reported having used prescription stimulants not prescribed to them.

Most students who had used these drugs reported initiating use after entering college (74.9% cocaine; 68.4% methamphetamine; 54.8% prescription stimulants). Cocaine, meth, and prescription stimulants were used more frequently by students who were 21 years of age or older compared to those under 21 (King & Jun, 2018)<sup>1</sup>.

#### USE OF STIMULANTS IN THE TREATMENT POPULATION Treatment Epicode Data Set

#### Treatment Episode Data Set

Data from the Treatment Episode Data Set (TEDS) indicate that methamphetamine was the most widely used stimulant in Indiana's substance use treatment population. In nearly one-fourth (23.7%) of treatment

admissions in Indiana methamphetamine use was reported in 2016; this represents a significantly higher proportion compared to the rest of the country (16.5%, P < .001). Methamphetamine use was more commonly reported among women, whites, and younger adults (see Table 6.2). The use of methamphetamine in Indiana's treatment population increased by more than 150% since 2007 (see Figure 6.7).

Cocaine was the second most frequently used stimulant in Indiana's treatment population and reported in 12.1% of treatment admissions in 2016; a percentage significantly lower than that noted for the rest of the nation (17.7%, P < .001). Cocaine use was reported more often by women, black individuals, and persons 45 years of age and older (see Table 6.2). The use of cocaine among those in treatment dropped nearly 50% since 2007 (see Figure 6.8).

Misuse of prescription stimulants was comparatively low within this population. In 1.7% of Indiana treatment admissions, misuse of these drugs was reported in 2016; a percentage similar to that for the rest of the country (1.6%). Aside from a spike in 2011-2012, the misuse of prescription stimulants by Indiana's treatment population has changed little over the past 10 years (see Figure 6.9). Women and whites entering treatment were more likely to report misuse (see Table 6.2).

<sup>1</sup>Twenty-four colleges participated in the 2018 survey; results are based on nonrandom sampling and are not representative of all college students in Indiana.

		Methamphe	etamine	Coc	aine	Prescription	Stimulants
		N	%	N	%	Ν	%
Gender	Male	2,556	20.1%	1,463	11.5%	176	1.4%

#### **HEALTH CONSEQUENCES**

The use of cocaine, meth, and prescription stimulants can all result in serious health consequences if used at high doses, especially over long periods of time. Ingesting large amounts of any of these drugs can result in serious cardiovascular, nervous system, or gastrointestinal complications, overdose, and in severe cases, death. Consuming stimulants can also lead to psychotic-like symptoms and paranoia, which, depending on the drug used, can be permanent. Meth use is particularly damaging to the body with long-term use associated with brain, liver, and kidney damage and serious dental problems (i.e., meth mouth). Although stimulant users who inject place themselves at particularly high risk for contracting blood-borne illnesses such as HIV and hepatitis, all stimulant users are at heightened risk for these illnesses as these drugs can severely impair judgment and lead to risky sexual behaviors with infected partners (NIDA, 2016a, 2017, 2018).

#### LEGAL CONSEQUENCES Indiana State Police Meth Lab Seizures

Much of the meth currently consumed in the U.S. is produced in "superlabs," most of which are located in Mexico (NIDA, 2017). However, because meth can be produced using easily accessible ingredients such as pseudoephedrine, lithium batteries, and fertilizer, among others, a certain amount of the drug is produced locally in small, clandestine laboratories or through the use of a one-pot or "shake and bake" method where all ingredients are combined into one container (often a 2-liter or 20-ounce plastic soda bottle) and shaken (Blostein et al., 2009; Greene, Williams, & Wright, 2010). Clandestine labs create significant risks for persons who live in and around them due to the toxic fumes, chemical contamination, and risk of fires and explosions that are associated with this form of meth production, while the toxic residue from shake-and-bake production remaining in soda bottles is often dumped along roadways (Blostein et al., 2009; Greene, Williams, & Wright, 2010; Messina, Marinelli-Casey, West, & Rawson, 2007; Petit & Curtis, 1999). In 2018, the Indiana State Police (ISP) seized 192 clandestine meth labs and made 81 meth lab arrests. In the majority of the meth labs seized (n=164, 88%), the one-pot method was used. The number of meth labs seized in the state has seen a dramatic decline, particularly in the past two years with the number of labs seized in 2018 representing a 89% decrease from the peak number of seizures in 2013 (see Figure 6.10) (ISP, 2018).

**Figure 6.10** Number of Clandestine Methamphetamine Labs Seized and Number of Arrests Made at Methamphetamine Labs by the Indiana State Police (Indiana Meth Lab Statistics, 2009-2018)

Source: ISP, 2018

# Children Taken from Methamphetamine Lab Homes

In addition to the health-related and criminal consequences, meth use can have serious social impacts on children and families in ways similar to other forms of substance abuse. These include contributing to increased interpersonal conflicts, violence, financial problems, and poor parenting (Sommers, Baskin, & Baskin-Sommers, 2006). Other social effects of meth use include incarceration of parents and placement of children in protective custody. According to ISP data, the number of children who were taken from meth lab homes in Indiana peaked in 2013 (440 children), but dropped to 14 in 2018 (see Figure 6.11) (ISP, 2018).

## MENTAL HEALTH AND SUICIDE IN INDIANA

#### INTRODUCTION

Good mental health is essential to a person's wellbeing. It affects our ability to adapt to change, cope with challenges, live productively, and have healthy relationships. Mental disorders are conditions characterized by alterations in thinking, mood, perception, and/or behavior (Office of Disease Prevention and Health Promotion, 2018). Mental illness collectively refers to all diagnosable mental disorders, including, but not limited to:

- Anxiety disorders (e.g., generalized anxiety disorder, phobias)
- Mood disorders (e.g., major depression, bipolar disorder)
- Psychotic disorders (e.g., schizophrenic spectrum and other psychotic disorders)
- Behavior disorders (e.g., ADHD, conduct disorder)
- Personality disorders (e.g., borderline or antisocial personality disorders)
- Substance-related and addictive disorders (e.g., alcohol and other substance use disorders) (Substance Abuse and Mental Health Services Administration, SAMHSA, 2019)

According to the Centers for Disease Control and Prevention (CDC, 2018b), more than 50% of Americans are diagnosed with a mental illness at some point during their lifetime, and 20% experience a mental disorder in a given year. Mental illness is associated with a number of other chronic diseases, as well as substance use (alcohol, tobacco, and drugs) and suicide (CDC, 2013; Kessler, 2004; SAMHSA, 2002, 2013). The 2017 National Survey on Drug Use and Health (NSDUH) reported that of the 46.6 million U.S. adults who experienced a mental illness in the past year, 8.5 million (or 3.4%) also had a substance use disorder (SAMHSA, 2017a). Individuals diagnosed with cooccurring mental health and substance use disorders tend to have more complex problems, often resulting in a more chronic and persistent course of illness, poorer response to treatment, and higher rates of substance abuse relapse (Bradizza, Stasiewicz, & Paas, 2006; Davidson & White, 2007; Kessler, 2004).

For this chapter, we compiled available state-level data on indicators related to mental health. Definitions of specific terms used in this chapter can be found in Appendix 7A.

#### PREVALENCE OF PSYCHOLOGICAL DISTRESS IN INDIANA National Survey on Drug Use and Health

The National Survey on Drug Use and Health (NSDUH) measures the prevalence of mental illness in the U.S. population. It defines 'any mental illness' (AMI) as having a diagnosable mental, behavioral, or emotional disorder, other than a developmental or substance use disorder; 'serious mental illness' (SMI) then refers to having a mental illness that results in serious functional impairment (2017a).

According to estimates from the 2017 NSDUH, one in five Indiana adults (20.9%) reported having any mental illness in the past year (95% CI [Confidence Interval]: 18.9-23.1), compared to 18.6% (95% CI: 18.2–18.9) of U.S. adults. Past-year prevalence rates for serious mental illness were similar in Indiana (5.2%, 95% CI: 4.4-6.2) and the nation (4.4%, 95% CI: 4.2-4.6). For AMI and SMI prevalence rates by age group, see Figure 7.1 (SAMHSA, 2017a).

**Figure 7.1** Percentage of Indiana and U.S. Population (18 Years and Older) Reporting Any Mental Illness (AMI) or Serious Mental Illness (SMI) in the Past Year, by Age Group (National Survey on Drug Use and Health, 2017)

Source: SAMHSA, 2017a

Among adults ages 18 and older, past-year prevalence rates of AMI and SMI remained fairly stable

between 2009 and 2017 (see Figure 7.2) (SAMHSA, 2017a).

Source: SAMHSA, 2017a

In 2017, 7.0% of Indiana adults (95% CI: 5.8-8.5) reported having had at least one major depressive episode (MDE) in the past year (U.S.: 6.1%, 95% CI: 5.8–6.3). For rates by age group, see Figure 7.3 (SAMHSA, 2017a).

The percentage of adults with a major depressive episode remained stable between 2008 and 2017 (see Figure 7.4) (SAMHSA, 2017a).

**Figure 7.3** Percentage of Indiana and U.S. Population Reporting at Least One Major Depressive Episode in the Past Year, by Age Group (National Survey on Drug Use and Health, 2017)

Note: There are minor wording differences in the questions in the adult and adolescent MDE modules. Therefore, data from youths ages 12 to 17 were not combined with data from persons ages 18 or older to produce the total MDE estimate. Source: SAMHSA, 2017a

**Figure 7.4** Percentage of Indiana and U.S. Population (18 Years and Older) Reporting at Least One Major Depressive Episode in the Past Year (National Survey on Drug Use and Health, 2008–2017)

Source: SAMHSA, 2017a

In 2017 more than 8.5 million U.S. adults (or 3.4%) had a co-occurring mental illness and substance use disorder; the prevalence rate was particularly high in young adults ages 18 to 25 (6.9%) (SAMHSA, 2017a). State-level estimates for co-occurring disorders are currently not available from the NSDUH.

# Behavioral Risk Factor Surveillance System

According to the 2017 Behavioral Risk Factor Surveillance System (BRFSS), 23.5% of adults in Indiana reported ever being told that they had depression (U.S.: 20.5%). Among Hoosiers, having a history of depression was greatest among females, individuals who identified as multiracial, and individuals under the age of 65 (see Table 7.1) (CDC, 2017a).

#### Youth Risk Behavior Surveillance System

Based on the 2015 Youth Risk Behavior Surveillance System (YRBSS), the percentage of high school students who reported "stopping some of their normal activities during the past year due to feeling sad or hopeless almost every day for two weeks" did not differ significantly between Indiana and the nation (IN: 29.4%; U.S.: 29.9%). Rates were higher for females (39.2%) and students who self-identified as gay, lesbian, or bisexual (57.8%). For rates by student characteristics, see Table 7.2 (CDC, 1991-2015). **Table 7.1** Percentage of Indiana and U.S. Population(18 Years and Older) Reporting a History of Depression(Behavioral Risk Factor Surveillance System, 2017)

		Indiana (95% CI)
Gender	Male	17.0% (15.7-18.2)
	Female	29.6% (28.2-31.1)
Race/Ethnicity	White	24.9% (23.8-26.0)
	Black	18.8% (15.5-22.0)
	American Indian or Alaskan Native	20.3% (11.2-29.4)
	Multiracial	30.3% (22.7-37.9)
	Hispanic	11.1% (8.2-13.9)
Age Group	18-24	26.2% (22.4-30.0)
	25-34	25.9% (23.1-28.7)
	35-44	23.8% (21.2-26.3)
	45-54	24.8% (22.7-27.0)
	55-64	26.5% (24.6-28.5)
	65+	15.8% (14.6-17.0)
Total		23.5% (22.5-24.4)

		Indiana (95% CI)	U.S. (95% CI)
Gender	Male	19.8 (17.5–22.3)	20.3 (18.9–21.8)
	Female	39.2 (33.6–45.0)	39.8 (36.5–43.2)
Race/Ethnicity	White	28.4 (25.8–31.1)	28.6 (25.8–31.5)
	Black	31.2 (22.2–41.8)	25.2 (21.7–29.1)
	Hispanic	36.8 (27.8–46.8)	35.3 (32.3–38.4)
Grade	9th	26.9 (23.0–31.2)	28.4 (25.9–31.0)
	10th	33.3 (27.8–39.3)	29.8 (26.6–33.1)
	11th	31.8 (25.7–38.7)	31.4 (28.3–34.8)
	12th	26.0 (21.6–30.8)	30.0 (27.5–32.6)
Sexual Identity	Heterosexual	25.2 (22.5–28.0)	26.4 (24.6–28.4)
	Gay, Lesbian, or Bisexual	57.8 (44.8–69.8)	60.4 (55.1–65.4)
	Not Sure	44.6 (28.6–61.9)	46.5 (41.2–51.8)
Total		29.4 (27.0–31.9)	29.9 (27.0–31.9)

**Table 7.2** Percentage of Indiana and U.S. High School Students (Grades 9 through 12) Reporting Feeling Sad orHopeless (Youth Risk Behavior Surveillance System, 2015)

Source: CDC, 1991-2015

Physically and verbally threatening behaviors, most often in the form of bullying, have been linked to a number of mental health problems in youth, primarily depression and anxiety (CDC, 2018a). The YRBSS collects information on some of these indicators. According to 2015 findings:

- 6.6% of Indiana high school students (95% CI: 4.8– 9.0) reported being threatened or injured on school property at least once with a weapon (U.S.: 6.0%, 95% CI: 5.2–6.8);
- 18.1% of Indiana high school students (95% CI: 15.0–21.6) reported being in a physical fight at least once (U.S.: 22.6%, 95% CI: 20.9–24.4);
- 15.7% of Indiana high school students (95% CI: 14.0–17.7) reported being electronically bullied (U.S.:15.5%, 95% CI: 14.5–16.6); and

 18.7% of Indiana high school students (95% CI: 16.1–21.5) reported being bullied on school property (U.S.: 20.2, 95% CI: 18.8–21.7) (CDC, 1991-2015).

#### **Indiana Youth Survey**

Results from the 2018 Indiana Youth Survey show that more than one-fifth of students in grades 6 through 12 reported feeling sad or hopeless. A substantial percentage of students also reported having considered suicide and even making a suicide plan in the past 12 months. For additional information, see Figure 7.5 (Gassman et al., 2018).

**Figure 7.5** Percentage of Students who Experienced Feeling Sad or Hopeless, Considered Suicide, or Made a Suicide Plan in the Past 12 Months, Grades 6 through 12 (Indiana Youth Survey, 2018)

Source: Gassman et al., 2018
### TREATMENT UTILIZATION National Survey on Drug Use and Health

According to estimates from the 2017 NSDUH, 20.9% of adult Hoosiers experienced a mental illness in the past year (Figure 7.1), and 17.6% received mental health services (SAMHSA, 2017a).

### **Uniform Reporting System**

In 2017, a total of 137,326 clients were served by the Indiana Division of Mental Health and Addiction (DMHA)—the state's mental health authority. Of those, nearly all (136,699) were treated in community settings rather than state hospitals (1,066). The client population was predominately non-Hispanic (90.7%), white (76.9%), and slightly more than half were female (52.9%) (SAMHSA, 2017b).

Clients included children who met the federal definition for severe emotional disturbance (SED) and adults who met the federal definition for serious mental illness (SMI). Over one-fourth (26.0%) of adults served by DMHA received services for co-occurring mental illness and substance use disorders, as did 3.0% of the children (SAMHSA, 2017b). For more detailed client information, see Table 7.3.

### SUICIDE

Suicide is a public health issue that is often associated with mental illness and substance use (CDC, 2017b; Lipari, Hughes, & Williams, 2016). Prior to actually making a suicide attempt, individuals may often spend significant amounts of time thinking about and planning how they might die by suicide.

Suicide is one of the top 10 leading causes of death for persons between the ages of 10 and 64 (National Center for Health Statistics, 2017). Although younger individuals are more likely to think about suicide, suicide deaths most frequently occur in adults between the ages of 45 and 54 (CDC, 2017b).

### National Survey on Drug Use and Health

According to 2017 NSDUH findings, 5.0% of Indiana adults (95% CI: 4.2–6.1) reported having serious thoughts of suicide in the past year; an estimate similar to the U.S. rate of 4.2% (95% CI: 4.0–4.4). This was particularly prevalent among young adults ages 18 to **Table 7.3** Demographic Characteristics of Adults withSMI and Children with SED Served by the IndianaDivision of Mental Health and Addiction, FY 2017

Gender	Male	47.1%
	Female	52.9%
Race	White	76.9%
	Black	14.6%
	Other/Unknown	8.5%
Ethnicity	Hispanic	6.3%
Age Group	Children 0-17	39.7%
	Adults 18+	60.3%
Medicaid Status	Medicaid only	69.0%
	Both Medicaid and other funds	19.0%
	Non-Medicaid	12.0%
Total		137,326 (100%)

Source: SAMHSA, 2017b

25 (IN: 11.1%, 95% CI: 9.0–13.5; U.S.: 9.6%, 95% CI: 9.2–10.1) (SAMHSA, 2017a).

### Youth Risk Behavior Surveillance System

Based on estimates from the 2015 YRBSS, nearly one in ten high school students attempted suicide in the past year. The overall percentages were similar in Indiana (9.9%) and the U.S. (8.6%). Rates were particularly high for students who self-identified as gay, lesbian, or bisexual (34.2%). For prevalence rates by gender, race/ ethnicity, sexual identity, and grade level, see Table 7.4 (CDC, 1991-2015).

### **Suicide Mortality**

Suicide deaths both nationally and in Indiana have increased significantly since 1999 (IN: 10.4; U.S.: 10.5, per 100,000 population). According to 2017 estimates, Indiana's age-adjusted suicide mortality rate of 16.4 per 100,000 population (95% CI: 15.4–17.4) was significantly higher than the U.S. rate of 14.5 (95% CI: 14.3–14.6). For 10-year trends, see Figure 7.6. Most suicide deaths occurred in males, whites, and non-Hispanics (see Table 7.5). For county-level age-adjusted annual suicide mortality rates, refer to Map 7.1 (CDC, 1999-2017).

		Indiana (95% CI)	U.S. (95% CI)	
Gender	Male	Male 8.7 (6.0–12.5)		
	Female	10.9 (8.3–14.1)	11.6 (9.7–13.7)	
Race/Ethnicity	White	8.7 (6.5–11.5)	6.8 (5.5–8.4)	
	Black	14.5 (8.8–23.1)	8.9 (6.7–11.9)	
	Hispanic	15.5 (8.9–25.8)	11.3 (9.9–13.0)	
Grade	9th	12.8 (7.7–12.7)	9.9 (8.5–11.5)	
	10th	11.4 (8.6–14.9)	9.4 (7.6–11.6)	
	11th	10.0 (6.4–15.2)	8.0 (6.8–9.5)	
	12th	5.0 (2.7–9.0)	6.2 (4.9–7.9)

### Appendix 7A Definitions and Explanations

<u>Any Mental Illness (AMI):</u> "AMI among adults aged 18 or older is defined as currently or at any time in the past 12 months having had a diagnosable mental, behavioral, or emotional disorder (excluding developmental and substance use disorders) of sufficient duration to meet diagnostic criteria specified within the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)" (SAMHSA, 2017a).

Serious Mental Illness (SMI): "SAMHSA defined SMI as persons aged 18 or older who currently or at any time in the past year have had a diagnosable mental, behavioral, or emotional disorder (excluding developmental and substance use disorders) of sufficient duration to meet the criteria specified within DSM-IV that has resulted in serious functional impairment, which substantially interferes with or limits one or more major life activities" (SAMHSA, 2017a).

Major Depressive Episode (MDE): "MDE, as defined in NSDUH, is based on the definition of MDE in the DSM-IV (APA, 1994) and is measured for the lifetime and past year periods. Lifetime MDE is defined as having at least five or more of nine symptoms of depression in the same 2-week period in a person's lifetime, in which at least one of the symptoms was a depressed mood or loss of interest or pleasure in daily activities. Respondents who had MDE in their lifetime were defined as having past year MDE if they had a period of depression lasting 2 weeks or longer in the past 12 months while also having some of the other symptoms of MDE. It should be noted that, unlike the DSM-IV criteria for MDE, no exclusions were made in NSDUH for depressive symptoms caused by medical illness, bereavement, or substance use disorders" (SAMHSA, 2017a).

<u>Depression:</u> "Has a doctor, nurse, or other health professional EVER told you that you had...a depressive disorder, including depression, major depression, dysthymia, or minor depression?" (CDC, 2017a).

Feeling Sad or Hopeless:

- a) "Felt sad or hopeless (almost every day for 2 or more weeks in a row so that they stopped doing some usual activities during the 12 months before the survey)" (CDC, 1991-2015).
- b) "During the past 12 months, did you ever feel so sad or hopeless almost every day for 2 weeks or more in a row that you stopped doing some usual activities?" (Gassman et al., 2018).

<u>Suicide Attempts:</u> "Attempted suicide one or more times during the 12 months before the survey" (CDC, 2017b).

<u>Suicide Deaths:</u> Suicide (intentional self-harm) deaths include ICD-10 codes U03.0 (Terrorism involving explosions and fragments), U03.9 (Terrorism by other and unspecified means), X60-X84 (Intentional self-harm).

### METHODS

This annual report describes the consumption and consequences of alcohol, tobacco, and other drugs in Indiana. We analyzed patterns within Indiana's general population, and compared them to patterns found among the U.S. population. Based on discussions with the State Epidemiological Outcomes Workgroup (SEOW), we have reviewed consumption and consequences data for the following drugs: alcohol, tobacco, marijuana, opioids, and stimulants. Additionally, we examined indicators of mental health and suicide in Indiana.

Our research team completed statistical analyses on publicly available local and national data sets using Statistical Package for the Social Sciences (SPSS) and Statistical Analysis System (SAS) software. For surveys that do not have publicly available data sets, we conducted statistical analyses using online analysis software and/or analysis tables provided by the agencies that conducted the data collection. Whenever possible, we made statistical comparisons across gender, racial/ethnic, and age groups for both drug-consumption behaviors and drug-use consequences. For all comparisons, a *P* value of .05 or less, or the 95 percent Confidence Interval (CI) was used to determine statistical significance.<sup>1</sup>

Prevalence rates and other statistics may be presented somewhat differently across chapters, depending on the data sources that provided the information.

We used two guidelines to determine potential priorities. The first guideline was statistical significance. Statistical significance is a mathematical concept used to determine whether differences between groups are true or due to chance. Significance in this context does not necessarily mean "meaningful" and does not convey practical or clinical importance. Specific drug consumption and consequence patterns that place Indiana statistically significantly higher than the United States were used as markers for areas that could potentially benefit from intervention.

The second guideline was clinical or substantive significance; i.e., consumption behaviors or drug-use

consequences that are trending toward a higher frequency within a particular group of Hoosiers, such as a specific gender, race/ethnicity, or age group.

### **DATA SOURCES**

The data for these analyses were gathered from various publicly available federal, state, and local-level surveys and administrative data sets. In order to compare Indiana with the nation as a whole and to determine trends in drug use and drug-related consequences over time, we selected, whenever possible, surveys and data sources that had at least two years' worth of data available. In all cases, the most recent findings were included.

### CONSIDERATIONS

This report relies primarily on the data sources listed below. These are either 1) publicly available sources that our researchers could access and analyze for this year's state epidemiological report or 2) agency data sources that were provided specifically to the SEOW. Because of the nature of the available data, there are significant limitations to the interpretations presented:

- Consistent comparisons across data sources are not always possible due to the nature of the survey questions asked and information gathered.
- Inconsistencies may occur within classifications of demographic characteristics (e.g., age ranges, racial categories, grade levels).
- Timeframes may be inconsistent for comparisons across substances and data sources (e.g., some data have longer gaps than others before they are made publicly available).
- State-level prevalence rates presented in national surveys are often estimated using statistical algorithms.
- Due to the reporting requirements for national databases, the data may not be representative of the actual population of either the state or the nation..

<sup>&</sup>lt;sup>1</sup>Throughout the chapters, we use the terms "significant," "significantly different," or "statistically different" to report a statistically significant difference between groups.

In future editions of this report, we will expand the data analysis as additional data sources are made available to the SEOW data analysis team.

### SEOW DATA SOURCES LIST

Following is a list of the data sources used in this report.

### Alcohol-Related Disease Impact (ARDI) Database

The Centers for Disease Control and Prevention's (CDC) ARDI software generates estimates of alcohol-related deaths and years of potential life lost (YPLL) due to alcohol consumption. To do this, ARDI either calculates estimates or uses predetermined estimates of alcoholattributable fractions (AAFs)—that is, the proportion of deaths from various causes that are due to alcohol. These AAFs are then multiplied by the number of deaths caused by a specific condition (e.g., liver cancer) to obtain the number of alcohol-attributable deaths. Reports can be generated based on national or state-level data. **Description:** ARDI provides state and national estimates on alcohol-related deaths and years of potential life lost (YPLL) based on alcohol-attributable fractions.

Sponsoring Organization/Source: CDC.

Geographic Level: National and state levels. Availability: The database can be accessed at http:// nccd.cdc.gov/DPH\_ARDI/default/default.aspx. Trend: Pooled data averages from 2006–2010. Strengths/Weaknesses: ARDI may underestimate the actual number of alcohol-related deaths and years of potential life lost.

### Automated Reporting Information Exchange System (ARIES)

The Indiana State Police's ARIES is a central repository for all vehicle collisions reported in the state of Indiana, with and without alcohol involvement. Information on fatal accidents contained in the system is submitted to the national Fatality Analysis Reporting System. **Description:** ARIES contains data on vehicle crashes

with and without alcohol involvement.

**Sponsoring Organization/Source:** Indiana State Police (ISP).

**Geographic Level:** State and county levels. **Availability:** Upon request from the ISP. **Trend:** Annual; most recent data from 2017. **Strengths/Weaknesses:** The data are in aggregate format; comparisons by demographic variables such as age, gender, and race/ethnicity are not possible.

### Behavioral Risk Factor Surveillance System (BRFSS)

The CDC conducts the BRFSS annually with the assistance of health departments in all 50 states and the District of Columbia, Puerto Rico, Guam, and the U.S. Virgin Islands. BRFSS asks respondents ages 18 and older questions about health-related behaviors, including alcohol consumption and tobacco use. BRFSS results are available at the national and state levels as well as for selected metropolitan/micropolitan areas. BRFSS data allow for statistical comparisons across gender, age, race/ ethnicity, educational attainment, and income level.

The BRFSS has traditionally used random-digitdial telephone sampling of households with landline telephones. However, the increasing percentage of households abandoning their landline telephones for cell phones has significantly eroded the population coverage provided by landline-based surveys to 70% of the U.S. household population. To meet challenges for increasing non-coverage and decreasing response rates due to cell-phone-only households, BRFSS has expanded its traditional methodology to a dual frame survey of landline and cell phone numbers and has introduced a new weighting method called iterative proportional fitting, or raking. It would not be appropriate to directly compare estimates prior to 2011 with later estimates, due to different data adjustment methods and different sampling frames.

**Description:** BRFSS is an annual state health survey that monitors risk behaviors, including alcohol and tobacco consumption, related to chronic diseases, injuries, and death.

Sponsoring Organization/Source: CDC.

**Geographic Level:** National and state levels; selected metropolitan/micropolitan areas.

**Availability:** National and state data are available from the CDC at https://www.cdc.gov/brfss/brfssprevalence. **Trend:** Annual; most recent data from 2017.

Strengths/Weaknesses: CDC consistently works to test and improve BRFSS methodology in an effort to make findings result in more valid and reliable data for public health surveillance. Due to substantial changes in methodology starting with the 2011 survey, comparison of current estimates with estimates from previous years would not be appropriate.

### **Hospital Discharge Data**

The Indiana State Department of Health (ISDH) collects information on inpatients discharged from hospitals in Indiana. The data are publicly available in aggregate format and include information on hospitals, principal diagnoses and procedures, length of stay, total charges, etc.

**Description:** Hospital discharge data are publicly available in aggregate format. Dataset can be queried by primary diagnosis (ICD-10-CM codes), e.g., for alcohol- and drug-induced diseases.

Sponsoring Organization/Source: ISDH.

Geographic Level: Indiana.

**Availability:** Annual data are available at http://www. in.gov/isdh/20624.htm.

Trend: Annual; most recent data from 2017. Strengths/Weaknesses: The data are in aggregate format; comparisons by demographic variables such as age, gender, and race/ethnicity are not possible. Comparisons to years prior to 2016 are not possible due to the ICD-9-CM to ICD-10-CM switch that occurred on October 1, 2015.

### Indiana Adult Tobacco Survey (IATS)

The Indiana Adult Tobacco Survey (IATS), a survey by the ISDH Tobacco Prevention and Cessation Commission (TPCC), collects information on tobacco use, cessation attempts, and other related issues among Hoosiers ages 18 and older. The survey uses a random-sampling design; African-American and Hispanic adults as well as residents in more rural regions of the state are oversampled. Data are available by gender, race/ethnicity, age group, income level, educational attainment, Indiana region, health insurance type, and number of children in household. **Description:** This survey measures tobacco use among Indiana adults, and includes items on tobacco use, cessation, secondhand smoke, and awareness.

Sponsoring Organization/Source: ISDH/TPCC. Geographic Level: Indiana.

Availability: Datasets can be requested from ISDH/ TPCC; reports are available at http://www.in.gov/isdh/ tpc/2343.htm.

**Trend:** Biannual; most recent data from 2017. **Strengths/Weaknesses:** IATS uses a random-sample design, making findings representative of all Hoosier adults. Oversampling of African-American and Hispanic adults, as well as residents in more rural regions, provides more robust estimates for these population groups.

### Indiana College Substance Use Survey

The Indiana College Substance Use Survey was developed in 2009 by the Indiana Collegiate Action Network (ICAN) and the Indiana Prevention Resource Center (IPRC), with input from Indiana institutions of higher education and the Indiana State Epidemiological Outcomes Workgroup. The instrument was designed to assess prevalence of alcohol, tobacco, and other drug use; consequences of use; alcohol availability; and student perceptions of peer behaviors among Indiana college students. Information is available by gender, age category (under 21 vs. 21 or over), and type of institution (private vs. public). All two- and four-year colleges in Indiana are invited to participate in the survey. Results are based on nonrandom sampling and are not representative of all college students in Indiana.

**Description:** The survey measures the prevalence of alcohol, tobacco, and other drug use; consequences of use; alcohol availability; and student perceptions of peer behaviors among Indiana college students.

**Sponsoring Organization/Source:** Indiana Collegiate Action Network (ICAN); Indiana Prevention Resource Center (IPRC).

Geographic Level: Indiana.

Availability: Annual data are available at http://www. drugs.indiana.edu/indiana-college-survey/substance-usesurvey.

Trend: Annual; most recent data from 2018.

**Strengths/Weaknesses:** The survey utilizes a nonrandom sampling design; results, therefore, are not representative of all college students in Indiana.

### **Indiana Meth Lab Statistics**

The Indiana State Police (ISP) collects data on clandestine meth lab seizures in the state, including number of meth labs seized, number of arrests made during lab seizures, and the number of children located at/ rescued from meth labs. The information is then submitted to National Clandestine Laboratory Seizure System, a database maintained by the U.S. Drug Enforcement Administration and the El Paso Intelligence Center. State and county-level information can be requested from the ISP.

Description: ISP collects meth lab incidence data

including: Number of meth labs seized, number of arrests made during lab seizures, and the number of children located at/rescued from meth labs.

Sponsoring Organization/Source: ISP.

Geographic Level: State and county level.

Availability: Indiana data from ISP are available on request; national data can be accessed at http://www.dea. gov/resource-center/meth-lab-maps.shtml. Trend: Annual; most recent data from 2018. Strengths/Weaknesses: The data include all meth incidents, including labs, "dumpsites," or "chemical and glassware" seizures.

### Indiana Mortality Data and National Vital Statistics System (NVSS)

NVSS is a CDC-maintained data system that provides information on mortality rates by cause of death as coded in the World Health Organization's International Classification of Diseases, 10th Edition (ICD-10). Health departments in the 50 states, the District of Columbia, and U.S. territories provide CDC with data on deaths throughout the country. Using the guery system on CDC's website (CDC WONDER), researchers can compute mortality rates for deaths due to diseases and events associated with alcohol, tobacco, and other drug use (e.g., cirrhosis, lung cancer, heart disease, suicide, homicide, etc.) at the national, state, and county level. The system also allows for comparisons across gender, age, and racial groups. Indiana mortality data can also be requested directly from the Indiana State Department of Health (ISDH).

**Description:** NVSS contains mortality data from all U.S. states; the online database can be queried on number of deaths and death rates from alcohol- and drug-related causes. Indiana data can also be requested directly from ISDH.

**Sponsoring Organization/Source:** CDC's National Center for Health Statistics; ISDH.

**Geographic Level:** National, state, and county levels. **Availability:** National mortality data can be accessed by underlying cause of death (ICD-10 codes) from CDC at http://wonder.cdc.gov/mortSQL.html; state data are available on request from ISDH.

Trend: Annual; most recent data from 2017.

**Strengths/Weaknesses:** The strengths of the NVSS include availability of multiple years of data and the relatively large number of American Indian, Alaska Native, and other Native American respondents. However, a

primary weakness of the data is the quality of the race/ ethnicity information, particularly for the American Indian/ Alaska Native category, as data quality checks of the racial/ethnic distribution of the deceased in this category are lower than the distribution represented in Census estimates.

### Indiana Scheduled Prescription Electronic Collection & Tracking (INSPECT)

INSPECT is the state's prescription drug monitoring program. The secure database collects basic demographic information on the patient, the type of controlled substance prescribed, the prescribing practitioner, and the dispensing pharmacy. Each time a controlled substance is dispensed, the dispenser (e.g., pharmacy, physician, etc.) is required to submit the information to INSPECT. The program was designed to help address problems of prescription drug abuse and diversion in Indiana. By compiling controlled substance information into an online database, INSPECT performs two critical functions: (1) maintaining a warehouse of patient information to assist healthcare professionals in making treatment decisions; and (2) providing an important investigative tool for law enforcement to help prevent the possible diversion of controlled substances.

**Description:** INSPECT is Indiana's prescription drug monitoring program; the online database collects information each time a controlled substance is dispensed.

**Sponsoring Organization/Source:** Indiana Professional Licensing Agency (IPLA).

Geographic Level: Indiana and counties.

**Availability:** Number and rate of opioid dispensations aggregated at the county and Indiana-level is available from ISDH at https://gis.in.gov/apps/isdh/meta/stats\_layers.htm.

Trend: Annual; most recent 2018.

**Strengths/Weaknesses:** Data collection is statewide, and licensed dispensers (e.g., pharmacies, physicians) are required to submit information each time a controlled substance is dispensed. Dispensations aggregated at the county-level are approximate as some dispensations do not have a designated county FIPS code.

### Indiana Youth Survey (INYS)

The Indiana Youth Survey is an annual school-based assessment conducted by the Indiana Prevention Resource Center (IPRC) and funded through the Indiana Family and Social Services Administration/Division of Mental Health and Addiction. The survey is designed to monitor patterns of alcohol, tobacco, and other drug use; gambling behaviors; and risk and protective factors among Indiana middle and high school students, grades 6 through 12.

Caution is needed when comparing findings to previous years due to changes made to the survey in 2015. These changes, in addition to a revised cleaning methodology, make it difficult to draw accurate comparisons to the prevalence data from previous years.

The Indiana Youth Survey uses a convenience sampling design; i.e., the survey is open to all Indiana schools or school corporations, resulting in a large number of usable responses. However, the rate of participation varies widely across regions. In 2016, INYS also incorporated a random sampling process. The advantage of simultaneously collecting both random and convenience samples is that state-level estimates can be interpreted with greater confidence, even in areas with low participation rates.

INYS results are often compared to findings from the Monitoring the Future (MTF) survey conducted by the National Institute on Drug Abuse (http://www. monitoringthefuture.org/data/data.html). MTF is an ongoing study of youth behaviors, attitudes, and values about substance use; students in 8th, 10th, and 12th grades are surveyed annually.

**Description:** The IPRC manages the Indiana Youth Survey. The survey is administered to students (6th through 12th graders) annually in a number of schools throughout the state.

Sponsoring Organization/Source: IPRC; Indiana Family and Social Services Administration (FSSA)/Indiana
Division of Mental Health and Addiction (DMHA).
Geographic Level: Indiana state and regions.
Availability: Reports with data tables are available at http://inys.indiana.edu/survey-results.
Trend: Annual; most recent data from 2018.

**Strengths/Weaknesses:** School-specific survey results are valuable to participating schools and provide statewide prevalence estimates. Due to changes made to the survey, data cannot be compared to findings from previous years (prior to 2015).

### Indiana Youth Tobacco Survey (IYTS)

The CDC developed the National Youth Tobacco Survey as a way to estimate the current use of tobacco products among middle school and high school students in the United States. Student respondents are asked to describe their lifetime, annual, and current use of cigarettes and other tobacco products. The Indiana State Department of Health's Tobacco Prevention and Cessation Commission (ISDH/TPCC) oversees Indiana's version of the survey, which includes CDC core and recommended questions, as well as state-specific items. IYTS is conducted every other year (even years); findings allow comparisons across gender, race/ethnicity, and grade levels. **Description:** IYTS is Indiana's adapted version of CDC's NYTS. The surveys collect data from students in grades 6 through 12 on all types of tobacco use, exposure to secondhand smoke, and access to tobacco. **Sponsoring Organization/Source:** CDC; ISDH/TPCC.

Geographic Level: Indiana.

Availability: Data are available on request from TPCC, and annual reports can be accessed at http://www.in.gov/ isdh/tpc/2343.htm. National data are available at http:// www.cdc.gov/tobacco/data\_statistics/surveys/NYTS/. Trend: Biannual; most recent data from 2016. Strengths/Weaknesses: The IYTS provides detailed statewide information regarding youth knowledge, attitudes, and behaviors. However, county-level data are not available.

### National Survey on Drug Use and Health (NSDUH)

NNSDUH is a national survey funded by the Substance Abuse and Mental Health Services Administration (SAMHSA) and designed to monitor patterns and track changes in substance use among U.S. residents 12 years of age and older. The survey asks respondents to report on use and misuse of substances including alcohol, tobacco, marijuana, cocaine, heroin, and prescription medications. Additionally, NSDUH asks respondents whether they received treatment for drug abuse or drug dependence during the past (prior) year. The survey also includes several modules of questions that focus on mental health issues.

Prevalence rates for substance use and specific mental health indicators are provided for the nation and each state. Raw data files from NSDUH surveys are publicly available; however, they do not allow for comparisons among states because NSDUH eliminates state identifiers in the process of preparing public-use data files. Tables with prevalence numbers and rates are prepared by SAMHSA's Center for Behavioral Health Statistics and Quality and can be accessed online. Data reports are available since 1994. There is usually a twoyear delay from the time of data collection to its availability.

In 2015, several changes were made to the NSDUH questionnaire and data collection process, causing some estimates not to be comparable with estimates from previous years. Items affected by these changes included binge drinking and prescription drug misuse. Due to these revisions, 2015 and later estimates cannot be compared to earlier years.

**Description:** NSDUH provides national and state-level estimates on the use of alcohol, tobacco, and illicit drugs (including nonmedical prescription drug use), as well as mental health indicators in the general population ages 12 and older.

Sponsoring Organization/Source: SAMHSA.

**Geographic Level:** National and state; some sub-state data are available using small-area estimation techniques. **Availability:** National and state data tables are available at the NSDUH website at http://www.samhsa.gov/data/population-data-nsduh.

Trend: Annual; most recent data from 2017.

**Strengths/Weaknesses:** State-level data do not allow for comparisons by gender or race/ethnicity.

### **Treatment Episode Data Set (TEDS)**

TEDS is a national database maintained by Substance Abuse and Mental Health Services Administration (SAMHSA) that records information about individuals entering treatment for substance abuse and/or dependence. State mental health departments submit data to TEDS on an annual basis. The information reported in TEDS includes age, race, ethnicity, gender, and other demographic characteristics, as well as information on the use of various substances. The data represent admissions rather than individuals, thus individuals may be admitted to treatment more than once in a given year. TEDS data become publicly available approximately two years after the information is gathered. The format of the TEDS data allows for comparisons between Indiana and the United States by gender, race, and age group.

County-level TEDS data for Indiana are available from the Indiana Family and Social Services Administration (FSSA), Division of Mental Health and Addiction (DMHA). While TEDS data can provide some information on drug use and abuse patterns both nationally and at the state level, the population on which the data are based may not be representative of all individuals in drug and alcohol treatment. For Indiana, TEDS data are limited to information on individuals entering substance abuse treatment who are 200% below the federal poverty level and receive state-funded treatment.

**Description:** TEDS provides information on demographic and substance abuse characteristics of individuals in alcohol and drug abuse treatment. Data are collected by treatment episode. A treatment episode is defined as the period from the beginning of treatment services (admission) to termination of services.

Sponsoring Organization/Source: SAMHSA; FSSA/ DMHA.

Geographic Level: National, state, and county-level. Availability: National and state TEDS data were acquired from SAMHSA's Drug & Alcohol Services Information System at http://wwwdasis.samhsa.gov/dasis2/teds.htm; county-level data available from FSSA upon request. Trend: Annual; most recent data from 2016 (from SAMHSA) and 2018 (from DMHA).

**Strengths/Weaknesses**: In Indiana, these data are not representative of the state as a whole, as only individuals who are at or below the 200% poverty level are eligible for treatment at state-registered facilities.

### Youth Risk Behavior Surveillance System (YRBSS)

The YRBSS is a national survey of health-related behaviors among students in grades 9 through 12. The CDC conducts the survey biannually with the cooperation of state health departments throughout the nation. Student respondents are asked to describe whether they have engaged in numerous behaviors that could pose a danger to their health, including the use of alcohol, tobacco, and other drugs. CDC's online database allows comparisons between Indiana and the United States on gender, race/ ethnicity, and grade level. Data for the YRBSS are available every other year (odd years), with a one-year lag between the end of data collection and the publication of results. Though YRBSS data for some states are available from 1991, Indiana started participating in data collection in 2003. Availability of state-level results is dependent upon sufficient participation to achieve an adequate response rate to weight the data.

**Description:** This biannual national survey monitors health risks and behaviors among youth in grades 9 through 12.

Sponsoring Organization/Source: CDC.

Geographic Level: National and state level. Availability: National and state-level data are downloadable from selected published tables on the CDC website at http://nccd.cdc.gov/YouthOnline/App/Default. aspx.

**Trend:** Biannual; most recent data from 2015. **Strengths/Weaknesses**: Availability of state-level results is dependent upon sufficient participation; Indiana's response rates in 2013 and 2017 were too low and, therefore, did not yield any estimates.

Additional information on these datasets, including how to access them, can be found in Appendix I.

### APPENDIX III: CLUSTER ANALYSIS

We completed a statewide cluster analysis to determine the drug combinations that are most frequently used by polysubstance users who are in treatment. Results were based on the 2018 Treatment Episode Data Set, which we received from the Indiana Family and Social Services Administration (FSSA, 2018).

Drugs were grouped into nine (9) categories:

- Alcohol
- Marijuana
- Opioids (including nonprescription methadone, heroin, and other opiates/synthetics)
- Cocaine
- Methamphetamine
- Hallucinogens (including PCP and other hallucinogens)
- Stimulants (including amphetamines and other stimulants)
- Sedatives (including benzodiazepines, barbiturates, and sedatives/hypnotics)
- Other drugs (including inhalants, over-thecounter medications, other drugs, and unknown substances)

The analysis indicated that more than 70% of Hoosiers who received substance use treatment in 2018 reported misusing two or more drugs. Polysubstance users primarily fell into one of nine drug clusters (see Table III.1). The most commonly used combination of drugs included alcohol and marijuana. Alcohol combined with a drug that fell into the "other" drug category was the second most frequent grouping. Overall, marijuana

**Table III.1**Drug Combinations Used by IndianaPolysubstance Users (TEDS, 2018)

Drug Combinations	Number of Admissions	% of Admissions
Alcohol & Marijuana	4,148	17.6%
Alcohol & Other Drug	3,478	14.8%
Opioids & Methamphetamine	2,920	12.4%
Alcohol, Cocaine, & Marijuana	2,564	10.9%
Marijuana, Opioids, & Methamphetamine	2,528	10.7%
Opioids & Other Drug	2,452	10.4%
Marijuana & Methamphetamine	2,243	9.5%
Alcohol, Marijuana, & Methamphetamine	2,127	9.0%
Opioids & Sedatives	1,098	4.7%

Source: FSSA, 2018

was the drug most commonly combined with another substance and showed up in five out of the nine drug clusters; alcohol and methamphetamine each were represented in four clusters (see Table III.1).

The demographic composition of polysubstance users differed depending on which combination of drugs they used. Males made up a greater percentage of persons in seven of the nine drug clusters; however, women were more strongly represented in the group of individuals who used (1) an opioid and methamphetamine and (2) made up nearly 50% of persons who used a combination of an opioid and a sedative.

Whites composed the majority of polysubstance users in all of the nine drug use groupings. Blacks were most strongly represented among individuals who reported using alcohol, cocaine, and marijuana, making up over one third of persons in this category. Hispanics made up less than 10% of polysubstance users across all drug combination categories.

At least half of polysubstance users in eight of the nine polysubstance groups were between the ages of 25 and 44. Polysubstance users were somewhat younger if they reported using a combination of alcohol and marijuana (see Table III.2).

	Alcohol & Marijuana		Alcohol & Other Drug		Opioids & Meth		Alcohol, Cocaine, & Marijuana		Marijuana, Opioids, & Meth

### NARIJUANA COCAINE PRESCRIPTION DRUGS

### The Consumption and Consequences of Alcohol, Tobacco, and Drugs in Indiana: A State Epidemiological Profile 2018

### Indiana State Epidemiological Outcomes Workgroup

The Indiana State Epidemiological Outcomes Workgroup (SEOW) was established in April 2006 to review epidemiological data on the patterns and consequences of substance use and abuse in Indiana and to make recommendations to the State of Indiana regarding priorities for prevention funding for the following year. The priorities were developed based on a systematic analysis of available data, the results of which are detailed in this report.
